Abstract

Much attention has been paid to foreign investment spillovers in the literature, since inward foreign direct investment is regarded as a key engine of industrial growth and technological progress. However, little clear evidence has been found with regard to the relevance of geographic proximity for spillover effects, owing to a lack of location specific information. We therefore study the spatial component of spillover effects from foreign direct investment on total factor productivity (TFP) of domestic manufacturing firms in Vietnam from 2005 to 2010. Firm level TFP is estimated by applying a semi-parametric method. We geo-reference firms by using the smallest administrative unit (ward) and compile a unique data set containing information of firms location to exploit the variation in the presence of foreign firms around each domestic firm over time. Benefiting from enhanced spatial accuracy over previous studies, our empirical results using a first differenced two-stage least squares estimator are threefold. First, they show positive local spillover effects of foreign investment on domestic firms in the same industry. The effects are strongest and highly significant within a radius of 2 km to 10 km, and they show a distinct decay pattern within 10-50 km. Second, small and unproductive firms benefit disproportionately from the presence of foreign firms in their neighborhoods. Third, manufacturing vertical spillovers are also localized while vertical spillovers from the service sector are less geographically restricted.

1 Introduction

Foreign direct investment is seen as an important driver of technological progress in particular for developing countries due to spillover effects from foreign firms on the domestic industry. Spillovers may foster technological change and thus reduce the productivity gap between advanced multinational firms and incumbent establishments. As technologically superior foreign firms enter a developing country, local manufacturers start imitating products and production processes. People working for foreign firms switch jobs and join local firms transferring valuable know-how on production processes and organisational structures. Entry of foreign firms may also intensify competition in upstream local industries or improve the quality of intermediate goods for downstream industries. Since spillover effects from foreign invested firms are potentially beneficial for technological progress of domestic industries and conducive for economic growth particularly in emerging markets, it is crucial to understand the geographical scope and magnitude of spillover effects.

At least since Marshall (1920) we are aware of the importance of localisation of industries, for which he identifies three sources: labor market pooling, intermediate inputs and technological spillovers. Krugman (1991) further elaborated that geography, hence localisation of industry, clearly matters and that spillovers are much a local phenomenon. Firms benefit from being near other firms. Porter (1990, 2011) points out the importance of geographic concentration in industry clusters. Research on agglomeration economies emphasises the existence of information-based spillovers: The presence of knowledgeable neighbouring people or firms lead to significant learning processes (Glaeser, 2010). The importance of geographical proximity is emphasized e.g. by Orlando (2004) and Lychagin et al. (2010) in the context of R&D activity, Rosenthal and Strange (2003) on agglomerative externalities, Aharonson, Baum and Feldman (2007) on knowledge spillovers, Durranton and Overman (2005) on localization patterns, Rosenthal and Strange (2008) on human capital spillovers, and Greenstone, Hornbeck and Moretti (2010) for openings of large plants in the US.

This paper contributes to the literature by shedding more light on the relevance of spatial proximity with regard to spillover effects from foreign invested firms on the local industries' productivity growth. Essentially, we want to answer the question whether a domestic firm can absorb foreign know-how and increase its productivity from having foreign firms in its close surroundings. We complement the existing literature on FDI spillovers in one important way: we analyse the relevance of geographic proximity for FDI spillovers using exceptionally detailed geo-referenced information on location of domestic and foreign invested firms comprising an almost exhaustive register of Vietnamese firm data. The bulk of studies in this vast literature look at the presence of foreign firms within a certain industry and/or region yet are not able to analyse the spatial scope of spillovers due to existing data limitations – exact location information is usually not extractable from firm level survey data. Studies with a specific focus on localisation of FDI spillovers are scarce. Comparable examples in terms of accuracy of location data are Halpern and

Muraközy (2007) who present a similar study setup while employing a much smaller sample of Hungarian firms. Barrios et al. (2012) utilise an Irish plant level survey with detailed information on firms' location, but the sample comprises just 1790 firms. In an influential study, though with less geographic detail, Aitken and Harrison (1999) analyse the presence of foreign invested firms in 220 districts in Venezuela, but find no localised spillovers.¹

Adoption of advanced technologies from the technology frontier is seen as one of the main drivers of growth in developing countries (Acemoglu, Aghion and Zilibotti, 2006). In this respect, it is essential for domestic firms to make use of technology imitation opportunities and copy know-how from foreign direct invested companies. Productivity differences stem from disparities in technological knowledge. These differences may originate either from differences in R&D investment or the ability of adaptation to new technologies (see e.g. König, Lorenz and Zilibotti, 2012). The intensity of knowledge diffusion and the absorptive capacities of firms is seen as crucial channel for firms to catch up with technologically more advanced firms.

Knowledge diffusion conveyed by spillovers occurs through various channels. *First*, imitation or demonstration effects are an obvious source of knowledge transmission. Reverse-engineering of production processes by local firms seems a useful way to improve technical know-how (Görg and Greenaway, 2004; Smeets, 2008). *Second*, skill acquisition of local firms through the labor market improves their human capital. Proximity between firms increases the likelihood of physical contact between workers or product developers. Knowledge transition may work through a direct spillover from complementary workers or people switching jobs from a foreign invested firm to a domestic firm (Görg and Greenaway, 2004). This spillover channel that works through the labor market is seen as an important mechanism (Fosfuri, Motta and Rønde, 2001) and is supported by empirical work (Görg and Strobl, 2005; Markusen and Trofimenko, 2009). *Third*, competition from foreign firms in the same industry may put pressure on the local firm to use existing technologies more efficiently, when imitation of the foreign company's technology is hardly possible. Competition may also increase the speed of adoption of new technology (Görg and Greenaway, 2004). *Fourth*, spillover effects may materialise through vertical linkages (Smeets, 2008). Javorcik (2004) and Lin and Saggi (2007) emphasise the importance of direct technology transfers through backward linkages. Foreign invested firms are willing to transfer know-how to their suppliers in order to improve the quality and lower the prices of intermediate goods. Blalock and Gertler (2008) argue that a foreign firm even must make the technology widely available to several suppliers in order to avoid hold-up. Domestic firms may also become more productive through forward linkages in case they can buy technologically more advanced, qualitatively better, or less costly intermediate goods produced by multinationals in upstream sectors. Francois and Hoekman (2010) and Arnold, Javorcik and Mattoo (2011) emphasise the crucial linkages between production in goods and services, as services are often direct inputs into economic activities, determining

¹A detailed overview of related literature is provided in the next section.

the productivity of the fundamental factors of production, labor and capital.

Our proposition is that proximity between foreign invested and domestic firms crucially facilitates the know-how and technology transmission channels, and hence that geography and the localisation of industry matters for spillover effects. The entry of almost 2000 foreign invested firms to Vietnam in the period 2005 to 2010 presents a unique and suitable natural experiment to assess possible technology spillovers from foreign firms on the incumbent industries. We presume that the nearer a *foreign investment shock* occurs, the more intense potential spillover effects must be and the larger the productivity gains are for domestic firms. Spillover effects decay with increasing distance, as demonstrated by Orlando (2004), Halpern and Muraközy (2007), Greenstone, Hornbeck and Moretti (2010), Lychagin et al. (2010), or Barrios et al. (2012). Our research setup lets us more precisely estimate how localised these spillovers are in the context of foreign direct investment, benefiting from enhanced spatial accuracy over existing studies.

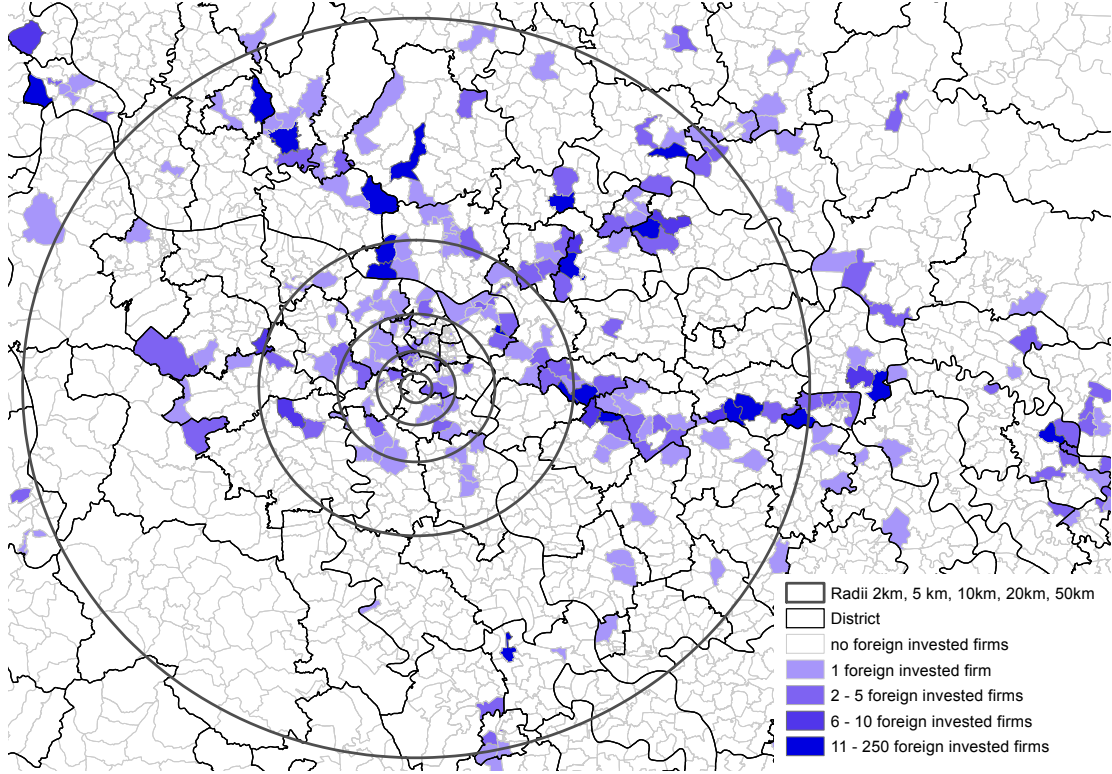

Our data set includes around 67'000 manufacturing firms in Vietnam over the period 2005 to 2010. Most importantly, we can determine the location of all firms by using information on the ward, the smallest administrative unit of Vietnam.² Since we know the location of all firms in Vietnam, we are able to observe the presence of foreign invested firms in close proximity to each domestic establishment over time. Figure 1 resembles the main idea of our paper for the case of Hanoi metropolitan area: we virtually draw circles of various radii around each domestic firm and measure the presence of foreign firms within its surroundings.

Our empirical strategy to estimate localised spillover effects consists of two stages. The first stage computes total factor productivity of firms from the parameters estimated by an industry specific production function method introduced by Levinsohn and Petrin (2003).³ The second stage causally identifies localised spillover effects from foreign invested firms on the local manufacturing firms using an estimation procedure first proposed by Anderson and Hsiao (1981), and controlling for possible confounding factors that may both influence location choice of foreign firms and domestic firm productivity. Additionally to absorbing the firm fixed effect by first differencing, we include industry fixed effects, province-time fixed effects, and time fixed effects. We rigorously examine different aspects relevant to the FDI spillover literature, yet with specific focus on the spatial scope of spillover effects, looking at horizontal – within industry – and vertical linkages working through the supply

²Vietnam comprises more than 11'000 wards. The median size of a ward with manufacturing activity is 8 km², representing the size of a circle with a radius of about 1.6 km. Measuring the size of wards weighted by the number of firms within a ward, the median size of wards is 4 km², a circle with a radius of just 1.12 km. The mean size of wards is then 8.2 km². More information on the spatial dimensions of our data and how we geo-reference firms is provided in section 4.2.

³The method of Levinsohn and Petrin (2003) is an extension of the framework initiated by Olley and Pakes (1996). Olley and Pakes (1996) decompose the residuals of the production into unobserved firm level productivity and zero-mean measurement errors. They calculate the unobserved productivity of an individual firm by using parameters estimated from the industry's production function. Other researchers such as Halpern and Muraközy (2007), Van Beveren (2012), and De Loecker and Warzynski (2012) define the unobserved firm level productivity (Olley and Pakes, 1996) as the total factor productivity. For consistency of the terminology, we also refer to the firm-productivity as total factor productivity.

Figure 1: Circles with different radii and foreign invested firms in 2010 in the Hanoi area

Notes: The map shows a representative example of circles around a firm with radii of 2km, 5km, 10km, 20km, and 50km. For each ward the number of foreign invested firms is indicated. Calculations of firms are based on the Vietnam Enterprise Survey 2010.

chain.

Our results affirm that spillover effects are indeed localised and quickly fade with increasing distance. Spillover effects seem to be strongest between 2 and 10 kilometres and attenuate rapidly across geographic space. Due to the great coverage of the data set including a large number of firms with less than 20 employees, we are able to analyse whether the local small and medium enterprises (SME) also benefit from foreign direct investments. Results indeed show strong support in favour of relevant spillover effects from foreign investments on the local SME sector, which is a stark results in terms of business development policy. Relatively unproductive firms also experience large productivity gains through foreign investment in their vicinity, yet there appears to be no within industry absolute convergence in productivity levels. With regard to vertical linkages operating through the supply chain among manufacturing firms, the results suggest that firms benefit from closely located foreign suppliers, but seem to be negatively affected by foreign backward linkages to downstream foreign firms.⁴ Furthermore, spillovers occurring through vertical links to service industries seem to be much less geographically limited.

The rest of the paper is organised as follows. Section 2 gives an overview of the existing

⁴We use the same definition of forward and backward linkages as Newman et al. (2015): forward linkages are upstream foreign suppliers; backward linkages are downstream foreign customers. This definition of *forward* and *backward* is implicitly referring to the perspective of the foreign firm.

literature on spillovers from foreign direct investment with a specific look at the studies that scrutinise the localisation of such effects. In addition, we present an overview of studies that look at the case of Vietnam. Section 3 elaborates the trends and patterns of foreign direct investment in Vietnam. In section 4 we present the data used. Section 5 describes the method applied to estimate firm level total factor productivity and presents the corresponding TFP estimates. Section 6 explains the identification strategy to estimate FDI spillover effects within the spatial framework and subsequently discusses the results, including the relevance of horizontal and vertical linkages for spillover effects. Finally, section 7 concludes.

2 Related Literature

Our paper contributes to a large international literature on spillover effects of foreign investment on the domestic economy. We present a short overview of the most related studies in two parts. The first part looks at the relevance of horizontal and vertical linkages, and the heterogeneity in effects. The second part sums up the contributions for the case of Vietnam.

2.1 Literature on FDI Spillovers

General results: A growing number of theoretical and empirical studies has shown that FDI is a crucial driver stimulating economic growth of the host country through the transfer of knowledge and technologies from advanced multinational enterprises (MNEs) to the domestic firms.⁵ Several comprehensive surveys of the literature come to mixed conclusions concerning the importance of FDI for the local economy. Görg and Greenaway (2004) investigate results of 40 studies on FDI spillover effects and attempt to draw general conclusions from the early literature. Their overall corollary is, first of all, that FDI is likely to be a key driver of economic growth by boosting capital formation and the quality of the capital stock in host countries. Multinational companies seem to bring best practice technology and management with them. They deduce that absorptive capacity of domestic firms and geographic proximity to multinationals are important determinants of spillover effects from foreign invested to domestic firms. Governments are hoping to stimulate these external benefits of FDI by offering incentives to foreign companies, suggesting that policy improvements should target the general conditions for doing business instead of particular industries or firms.

Smeets (2008) summarises the literature by concluding that the evidence on the magnitude, direction, and even existence of knowledge spillovers from foreign direct investment is ambiguous. Nonetheless, knowledge spillovers through channels like worker mobility,

⁵See e.g. Lim (2001), Borensztein, De Gregorio and Lee (1998), and Carkovic and Levine (2002) for an account of FDI and economic growth; Girma, Greenaway and Wakelin (2001) and Blomstrom and Kokko (2003) on FDI spillovers.

demonstration effects, and vertical linkages all seem to matter. Yet, the literature seems to agree on missing evidence for spillovers working through forward linkages, i.e. when foreign firms supply goods to domestic firms. Smeets (2008) emphasises the importance of distinguishing and specifically analysing different channels through which spillovers may occur.

Horizontal spillovers: Horizontal spillovers occur within an industry. Results are mixed. There are two main arguments. On the one hand, firms of the same industry may benefit from each other through face-to-face contacts and imitation of products or processes. On the other hand, firms in the same industry compete with each other. Competitive pressure may lead to more efficient use and quicker adoption of technologies, but it may also drive up the average cost curve due to fewer sales. Using a panel of 4'000 Venezuelan plants between 1976 and 1989, Aitken and Harrison (1999) find that foreign equity participation increases productivity of recipient plants with less than 50 employees, suggesting that plants benefit from productive advantages of foreign owners. Crucially, they also find a negative impact of foreign ownership on wholly domestically owned firms in the same industry. These large significant negative effects are brought by competitive pressures. Overall they conclude that there is no clear evidence of the existence of technology spillovers from foreign firms to domestically owned firms. In contrast to this early influential enquiry, Abraham, Konings and Sloomackers (2010) is one of the few studies that find positive within industry spillovers. They find that it was beneficial for total factor productivity of domestic firms when there was a certain presence of foreign competitors in analysis of more than 15'000 manufacturing firms in China in the years 2002 to 2004.

Vertical spillovers: Much attention has also been paid to the role of FDI spillovers to domestic firms through vertical linkages in the supply chain. Either a foreign firm supplies intermediate goods to a domestic firm or vice versa. A review of studies on the relevance of vertical linkages is conducted by Smeets (2008). Most studies find positive spillovers through backward linkages, but negative effects in the case of forward linkages. Javorcik (2004) analyses spillovers effects of FDI on productivity through backward and forward linkages using a firm level panel dataset from Lithuania. The author shows that spillovers are associated with projects that are shared between domestic and foreign firms, and not with fully foreign owned projects. Robust evidence for spillovers working through backward linkages is found, while intra-sectoral spillovers are absent in her study. Blalock and Gertler (2008) demonstrate the gain in productivity of Indonesian local suppliers through spillovers from foreign firms in downstream industries over the period of 1988 to 1996. In addition, the significance of inter-industry benefits to upstream domestic firms also seems to depend on the origin of the foreign investment in the downstream industry (Javorcik and Spatareanu, 2011).

Geographic Proximity: Spatial proximity between economic agents has become an important explanation of economies in production since the early stages of economic

research and was already investigated by Marshall (1920) in terms of specialised clusters of inputs (e.g. labor, materials, services), and technology spillovers. Halpern and Muraközy (2007) specifically investigate geographical distance as a determinant of FDI spillovers. The novelty in their study is the link between the TFP level (estimated by Levinsohn and Petrin, 2003) and the FDI spillovers in light of the distance from foreign firms to domestic firms in Hungary (1996–2003). They confirm that distance indeed matters for horizontal spillovers and emphasise the local nature of those. In addition, the authors extend the vertical and horizontal linkages proposed by Javorcik (2004) by weighting these variables with a function of distance between a foreign invested firm and a domestic firm. Though, a drawback of Halpern and Muraközy’s (2007) approach is the assumption on the functional form of the distance.⁶ A priori, using a functional form assumption for the distance $f(d)$ to weight foreign firms, it is unclear whether the effect of a foreign firm which has low output but is close to a domestic firm is similar in magnitude to an other foreign firm with a large output but which is far away. Besides not using a functional form assumption, our study also provides a higher degree of accuracy of firms’ locations. Furthermore, they are neither able to control for agglomeration effects such as the size of the labor market in the vicinity of each firm. Girma and Wakelin (2007) emphasise the strong intra-regional dimension of spillover effects in a study on the electronics industry in the UK. However, their study stays at a spatially rather crude level by dividing the UK into 10 regions, finding that horizontal spillovers occur within a region, but not outside (or across) the region.

In an investigation of spillovers from local and global R&D activities of domestic and foreign plants, Barrios et al. (2012) estimate distance decay effects by using the sample of Irish plant-level survey data from 1986 to 1996. Most relevant for our study, they also analyse local spillovers within circular areas around each plant. Considering all plants, they estimate significant local spillovers of R&D activity conducted in Ireland. Effects are strongest and significant within a radius of 10 km around a plant, but decay quickly beyond. Interestingly, domestic firms seem to benefit more from local R&D activities conducted by other domestic firms than those by foreign firms. Compared to Barrios et al. (2012), we employ a much larger data set and our geo-referenced firm location information is also more precise.⁷

⁶Halpern and Muraközy (2007) use a variety of functional form assumption to weight the horizontal and vertical linkages. Specifically, they use the following weighting functions of distance: $f_1(d) = 1/(1 + d/100)$ (the linkage to a foreign firm that is 100 km away from the domestic firm, is weighted by 0.5); furthermore, they also use two other functions with more pronounced decay patterns: $f_2(d) = 1/(1 + d/100)^2$ and $f_3(d) = 1/\ln(1 + d/100)$ as weighting functions.

⁷We employ a sample of 67’000 Vietnamese manufacturing firms, while Barrios et al. (2012) have a sample of just 1790 plants. In order to geo-reference firms, Barrios et al. (2012) use Irish district electoral divisions (DED) that have a mean size of 21 km². The Vietnamese wards that we use in the analysis have a mean size of 17.55 km²; when weighted by the number of firms within each ward, the mean size is even smaller at 8.21 km².

2.2 Literature on FDI Spillover Effects for the Case study of Vietnam

With a fast growing trend of foreign investment into Vietnam, extensive research has been conducted to study the role of FDI inflows for the local economy, whereof we specify the most relevant works.⁸

One of the early studies investigating FDI spillovers effects in Vietnam, Nguyen et al. (2008) use a large firm-level data set for the period 2000 to 2005 to study both horizontal and vertical spillover effects. They find evidence of positive backward spillover effects for the manufacturing sector and positive horizontal spillovers for the service sectors. They do not discover any evidence of backward and forward spillovers for the service sector. The study does not consider any spatial dimension in FDI spillovers. Instead the baseline empirical model merely uses the presence of foreign firms within an industry, incorporated in a Cobb-Douglas production function approach, as applied by most spillover studies.

Tran and Pham (2013) are the first to use a spatial econometric model for the case of Vietnam to investigate the importance of proximity for spillovers. Their study is much related to ours in the sense that they specifically examine geographical distance in the context of spillovers. Although they employ a spatial econometric model, they merely use the provinces as geographic unit of analysis. The spatial accuracy is hence considerably lower compared to our study. Tran and Pham (2013) find inter-regional spillovers to be four times larger than intra-regional spillovers. Confirming some findings in the literature, they estimate negative horizontal spillovers, positive backward and negative forward spillovers effects. Since their data set is limited to the period 2000 to 2005, the paper cannot provide results for the important period after the first Investment Law (2005) allowed more flexible types of foreign investment and investment license controls were decentralised to the provincial level.

Anwar and Nguyen (2014) analyse the performance of manufacturing firms in the eight regions⁹ of Vietnam affected by varying intensity of foreign investment. By applying 2SLS estimations and using manufacturing firm-level data for the period 2000 to 2005, Anwar and Nguyen (2014) suggest that through backward linkages, FDI spillovers positively influence only four of eight regions (i.e. Red River Delta, South Central Coast, South East and Mekong Delta River). They conclude that the impacts of FDI on the domestic economy varies considerably across regions.

Howard et al. (2014) investigate agglomeration effects of manufacturing clusters in Vietnam by using detailed information about the administrative units in the Vietnam Enterprise Survey (2002–2007).¹⁰ The study finds strong evidence of significant agglom-

⁸See e.g. Anwar (2011) for the analysis of FDI linkages and local firms' export activities. Another study for FDI in Vietnam (2001-2008) by Kokko and Thang (2014) indicate that the presence of foreign counterparts and foreign suppliers would increase the exit ratio of domestic firms.

⁹The government of Vietnam groups the provinces into eight large regions: Northwest, Northeast, Red River Delta, North Central Coast, South Central Coast, Central Highlands, Southeast, and Mekong River Delta.

¹⁰Their paper only considers the sample of firms in Vietnam (2002-2007) that includes registered firms

eration economies in Vietnam. Unlike many other studies, they do not find negative competition effects. Interestingly, foreign firms seem to benefit the most from firm clustering. While remarkably being one study that uses the ward (commune) as unit of analysis (other studies only analyse within province spillovers), they limit the analysis to clusters of firms within those communes, but not across. The spatial dimension of clusters (restricted to each ward) is hence captured in a non-continuous and very limited way. In contrast, we measure distances between wards and hence can model the whole agglomeration of firms to detect spillover effects to achieve a more thorough picture.

Newman et al. (2015) separate out productivity gains along the supply chain through direct transfers of knowledge and technology between linked firms. Importantly, they disentangle the spillovers through direct linkages, real technology transfers and other indirect effects. Their results confirm the importance of vertical linkages versus horizontal linkages with regard to spillover effects. More specifically, considering only direct linkages, they find that domestic firms experience positive productivity spillovers through their direct linkages with upstream FDI suppliers of inputs.

Complementing the existing literature, this paper proposes a simple though intriguing approach to evaluate localised spillover effects. We use the available detailed information on the location of foreign and domestic firms to evaluate how foreign investment in the surrounding area of domestic firms impacts on their performance.

3 Foreign Direct Investment in Vietnam

Since the *Doi Moi* (Renovation) in 1986, Vietnam’s development policy has sought to promote high economic growth, macroeconomic stability and international integration (UNIDO, 2011; Nguyen et al., 2006). Since the introduction of a new Law on Foreign Investment in 1987 with amendments in 1990, 1992, 1996, 2000, and 2005, Vietnam was constantly expediting foreign direct investment in order to strengthen capital formation and know-how transfer from more advanced economies through foreign firms.¹¹ In the earlier periods of opening up the country between 1988 and 2001, foreign investors were compelled to form joint-ventures with domestic firms, while after 2001 investments in the form of wholly foreign owned enterprises became more important (UNIDO, 2011). In 2005, the Law on Foreign Investment and the Law on Domestic Investment were unified into one common Investment Law that in combination with the unified Enterprise Law balanced the rights and treatment between domestic and foreign investors. Importantly, the 2005 Investment Law and 2005 Enterprise Law decentralised the control of investment license and business registration to provincial-level authorities.

Subsequently, in January 2007, Vietnam made another important step towards remark-
with more than 30 employees. The data records information on firms in 4’325 wards (communes) and 631 districts in 2007.

¹¹For a detailed discussion see e.g. Nguyen et al. (2006).

able international economic integration by acceding the World Trade Organization (WTO) that brought a further push to foreign investment and eventually resulted in registered USD 198 billion in foreign capital in 2011 (UNIDO, 2011). Foreign direct investment is concentrated mostly in the manufacturing and real estate sectors, accounting for 77 percent of total registered capital in foreign invested projects in 2011 (UNIDO, 2011). Manufacturing alone accounts for 58 % of all projects. The share of exports carried out by foreign invested firms jumped from 47 % to 57.2 % in 2007, then slightly decreasing to 54.2 % in 2010.

Table 1: Description of Foreign Firms in Process Manufacturing Sectors, Vietnam (2005–2010)

Year	Number	Δ (%)	Share of foreign invested firms (%)		
			Total output	Total labor	Total firms
2005	2654	14.10	43.51	36.35	11.05
2006	3032	14.24	46.01	39.38	11.29
2007	3516	15.96	45.23	41.41	11.32
2008	3958	12.57	44.42	42.77	10.31
2009	4353	9.98	41.66	42.64	9.74
2010	4587	5.38	44.47	44.73	9.80

Notes: Authors' compilation using the data drawn from the Vietnamese Enterprise Survey (2004–2010). The column "Number" is the number of foreign invested firms. The column Δ (%) is the percentage change in number of FIEs. The column "Share" is the Share of FIEs in Total Manufacturing firms' Total out, Total labor, and Total number.

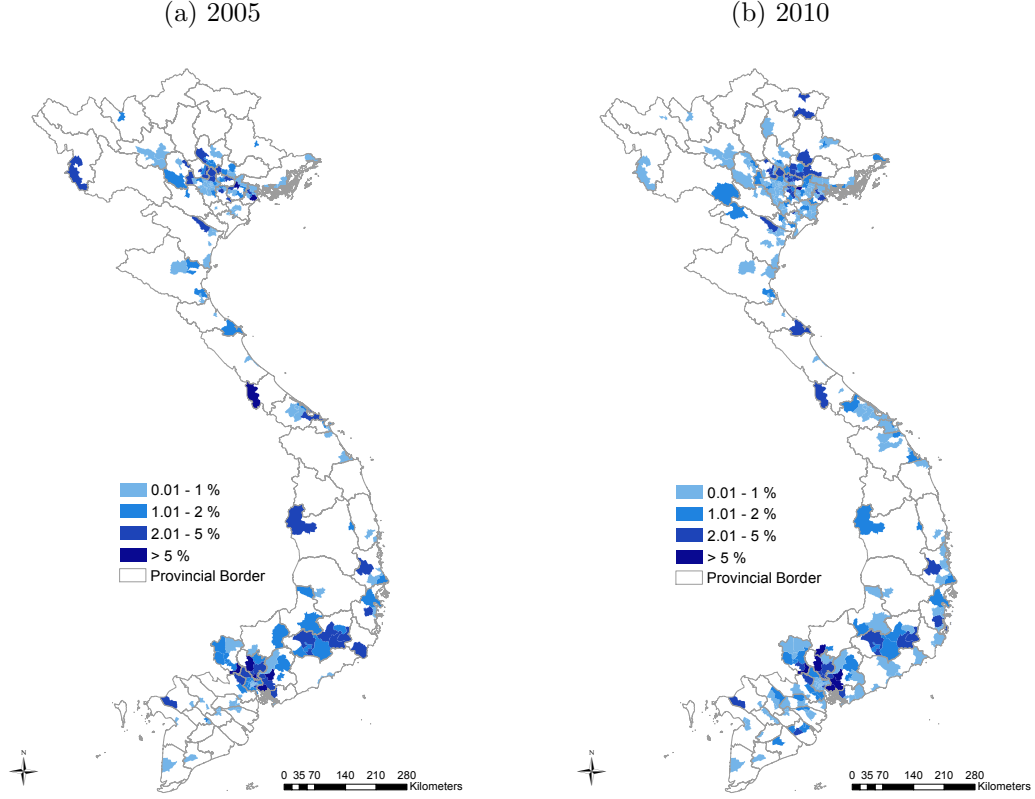

From 2005 to 2010, Vietnam attracted almost 2000 foreign invested firms (net increase) in the process manufacturing sectors. The international financial and economic crisis in 2007 and 2008 probably led many foreign companies to leave the country resulting in a very dynamic pattern of foreign investment during these years. Table 1 indicates that the increase in percent of number of foreign firms was 12.57% in 2008, then went down to merely 5.38% in 2010 while the number ranged from 14-16% in years before 2008.

Nevertheless, the crucial role of foreign invested firms in the process manufacturing sectors of Vietnam were still maintained with their significant shares in total output and in creating jobs (table 1). From 2005 to 2010, the output share of foreign firms was in the range of 41 to 46%, and hence rather stable over time. The number of workers employed by foreign manufacturers augmented from 36% in the year 2005 to almost 45% percent in the year 2010. This highlights the growing foreign presence in the labor market, where potential spillover channels are at play.

Figure 2 presents two maps with the regional allocation of foreign invested firms in the years 2005 and 2010 at the district level. It gives a clear indication of the dispersion of foreign presence across provinces. While in the year 2005 most of the foreign firms were located in the economic core areas around Hanoi Capital and Ho Chi Minh City, foreign activity moved more into suburban and rural areas over time up to 2010. This change in the regional distribution is possibly due to the more favourable investment environment mentioned above, for instance, the simpler licensing process and the more decentralised

authority control at provincial level. Figure B.1 in the appendix presents two similar maps using the share of revenue accruing to foreign firms in each district in the years 2005 and 2010. Figure B.3 in the appendix shows the same pattern for the labor force working for foreign invested firms.

Figure 2: Shares in Number of Foreign Invested Firms by District in Vietnam 2005 & 2010

Notes: Share of foreign invested firms per province is equal to the number of foreign invested firms in the province over the total number of firms. The maps are based on authors' calculations using the Vietnam Enterprise Survey 2005 & 2010. Administrative boundaries are based on Global Administrative Areas data (www.gadm.org). Several Vietnamese islands (e.g. Hoang Sa and Truong Sa) are not displayed due to the limitation of the GADM administrative boundaries data.

4 Data Description

This section gives a brief overview over the Vietnamese firm level data used (section 4.1) and explains in more detail the process of geo-referencing firms using the lowest Vietnamese administrative units (section 4.2).¹²

¹²See Nguyen (2016) for a detailed description of the Vietnamese manufacturing firm-level dataset from 2000-2010. See also Ha and Kiyota (2014) and Newman et al. (2015) for the descriptions of similar datasets respectively in the time frames from 2000-2009 and from 2009-2012.

4.1 Firm Level Data

To investigate the relevance of proximity for FDI spillovers in Vietnam, we use firm level data of process manufacturing industries in Vietnam drawn from the Vietnam Enterprise Survey for six consecutive years (2005–2010).¹³ The survey is a rich firm level database reporting yearly information on the legally registered enterprises that were in operation on the 31st of December each year. The data provides information about the establishment year, the location (at province, district, and ward level), the revenue, the profit before taxes, the total cost, the total wages, the number of workers, and the value of net fixed assets of each firm. The information on foreign investment is a dummy variable that is 0 for firms with no foreign investment and 1 for firms that are partly or fully foreign invested. Every firm in the data features a unique identification number and is compiled in an unbalanced panel over six years.

In order to exploit the location specific information of firms in the survey to examine spillovers at the local level, the firm level data is merged with the ward level administrative boundary data retrieved from the Global Administrative Areas database (GADM)¹⁴, and combined with the national input-output table of Vietnam (2007) assembled by the Vietnam General Statistics Office.¹⁵ Industry codes in the firm level data are specified by the 2-digit and 4-digit Vietnamese Standard Industrial Classification 1993 (VSIC 1993)¹⁶. To merge the firm-level data with the input-output table, we convert the 4-digit VSIC 1993 in the firm-level data to the 2-digit industrial classifications of the input-output table using the concordance table provided by the GSO. After merging the firm-level data with the input-output table, only firms in industries considered in the input-output data are included. It is assumed that the cost coefficients in the input-output table do not change over the studied periods.¹⁷

The yearly number of firms in each industry is presented in Table B.1. The resulting panel is unbalanced including 67’275 firms. Table B.1 in the appendix shows the number of firms in each industry.

¹³The census is annually conducted by the Vietnam General Statistics Office (GSO; www.gso.gov.vn) since 2000 till the current year. The data is published at an aggregated level in the Statistical Yearbook of Vietnam. We restrict our analysis to the years 2005 to 2010 because the new Law on Investment was introduced in Vietnam in 2005, and came into effects in 2006. Dataset after 2010 is not available to us. We would like to thank Pham Hanh at the Middlesex University (UK) for sharing the raw data with us, and Doan Thi Thanh Ha and Doan Hung at the Foreign Trade University (Vietnam) for discussing and sharing related documents.

¹⁴GIS shapefiles of administrative boundaries for Vietnam are available at www.gadm.org.

¹⁵The input-output table is available at:
<http://www.gso.gov.vn/default.aspx?tabid=512&idmid=5&ItemID=10752>.

¹⁶VSIC 1993 is provided by the GSO, and is similar to the International Standard Industrial Classification (ISIC Rev.3) provided by the United Nations. We use only the sample of industries for which 2-digits industry classification ranges from 15 to 37.

¹⁷This assumption follows Javorcik (2004).

4.2 Information on Firms' Location

To the best of our knowledge, we are the first to geo-reference the lowest administrative unit of the Vietnamese governing system in the Vietnam Enterprise Survey.¹⁸ Vietnam comprises more than 11'000 wards (communes). Since the Vietnam Enterprise Survey provides information on the province, the district, and the ward for each firm since 2005, we are able to geo-locate all of the 67'000 firms in our data set to their respective wards.¹⁹

The geographical scope of Vietnamese wards is remarkably small-scale. If we summarise the spatial dimensions of wards with at least one manufacturing firm domiciled, the median size is 7.94 km², while the mean size is 17.55 km² with a standard deviation of 34.78. Looking at the whole sample of firms and weighting the extent of wards by the number of firms based within, we receive a median size of just 3.99 km², and a mean of 8.21 km² with a standard deviation of 16.79. This is equal to a circle of radius 1.12 km². These numbers convey the geographic specifics at which we can perform the analysis and highlight the exceptionally small spatial scale used.

For each ward we determine the dyad wards within a certain radius and are thus able to calculate distances between firms with high accuracy.²⁰ This enables us to model the entire agglomeration of firms and to calculate industry specific statistics at various spatial dimensions for each firm in the data set.

5 Total Factor Productivity Estimation

Our empirical strategy consists of two steps that are prevalently applied in the spillover literature (see e.g. Combes and Gobillon, 2015, Newman et al., 2015, Anwar and Nguyen, 2014, and Barrios et al., 2012). In the first step discussed in this section, we estimate a production function within each industry and use the parameters estimated to impute firm level productivity. We then proceed to the second step of estimating spillover effects with a pronounced focus on spatial proximity between firms in the subsequent section.

¹⁸In order to map the ward information in the Vietnam Enterprise Survey on the Global Administrative Areas boundary shapefiles, we used the geocode command in Stata and mapped the wards according to the information on province, district, and ward. We then manually checked all 11'043 wards in ArcGIS for the correct geolocation. As the position of a ward we use the geographic centroid. For wards that were not located automatically by the geocode command, we extracted the coordinates by the use of Google Maps (<http://maps.google.com>).

¹⁹The survey data of manufacturing sectors records 5'662 unique codes of wards, 664 unique codes of districts, and 63 unique codes of provinces. These administrative units incorporate at least one observation, resulting in about 5'300 wards with no registered manufacturing firm in operation.

²⁰Since we cannot determine the exact location of firms within wards, we assume that they are all located at the geographical centroid of each ward. For firm dyads within wards we determine a minimal distance below 2km. Some studies randomly allocate firms within an administrative unit (e.g. Barrios et al., 2012). We abstain from this procedure since Vietnamese wards are sufficiently small units, and due to limited computing power.

5.1 TFP Estimation Methodology

We compute the firm-level productivity from the estimation of parameters in industry specific production functions as proposed and documented by Levinsohn and Petrin (2003) and Petrin, Poi and Levinsohn (2004), which are extensions of the Olley and Pakes (1996) methodology. More technical details on the methodological framework are explained in the Appendix A.

One important problem with firm-level productivity estimation is data related. Missing or non-positive values of investment flow reported in or imputed from micro data is a prevalent challenge in manufacturing firm data (Levinsohn and Petrin, 2003). The issue of lumpy investments is simply due to the typical high fixed cost in manufacturing sectors (i.e. start-up expenditures for machines and infrastructure) and does not allow for the inversion of the investment demand as the function of unobserved productivity. Firms in these sectors tend to invest large amounts of capital for expensive fixed assets when starting their business, but then delay the investment in the next year while the capital stock continues to depreciate. A feasible solution is to use intermediate inputs (materials and services) instead, which are demanded yearly, and can be observed or calculated from the information available in our data (see the description in Table A.1). Modifying the model of Olley and Pakes (1996) that uses investment as the proxy for unobserved productivity, Levinsohn and Petrin (2003) suggest to use the observed yearly smooth demand of the intermediate inputs as an alternative proxy.

We apply the method of Levinsohn and Petrin (2003) and Petrin, Poi and Levinsohn (2004) to estimate the coefficients of the production function and impute them to calculate firm level productivity, as it provides several advantages over ordinary least square, fixed effects and instrumental variables estimation (Van Beveren, 2012). First, the framework solves for simultaneity issues, and produces a consistent estimator.²¹ Second, the data required for intermediate input used as the proxy for unobserved productivity fits well with our data set, as discussed above.²² Levinsohn and Petrin (2003) apply the approximation in the third order polynomials for the unknown form of productivity shocks. Olley and Pakes (1996) note that either third or fourth polynomials show identical result in their estimations. Assumptions about the timing of the intermediate input choice may be applied to prevent the multi-collinearity of inputs (Akerberg, Caves and Frazer, 2006). We check the multicollinearity among inputs and non-parametric productivity in the actual data and the results reject the hypothesis of Akerberg, Caves and Frazer (2006).

²¹Levinsohn and Petrin (2003) show in detail the advantages of the method over OLS and FE methods.

²²The method of Levinsohn and Petrin (2003) and Petrin, Poi and Levinsohn (2004) has been widely applied in the literature. For a review of applications in international trade, see e.g. Feenstra (2015); a review of applications in research of agglomeration effects is provided in Combes and Gobillon (2015); Caliendo et al. (2015) shows the similarity of TFP calculations by the method of Levinsohn and Petrin (2003), Olley and Pakes (1996) and others; a very recent application of the method is conducted by Poczter (2016) who uses electricity consumption as a proxy for unobserved productivity.

5.2 Results of TFP Estimation

The estimation results of total factor productivity are shown in Table 2 in logarithmic form. The results reveal that the mean value of $\log(\text{TFP})$ is higher in foreign firms than domestic firms, hence foreign firms feature higher productivity than domestic firms. Additionally, annual growth in TFP differs between foreign and domestic firms: while domestic firms' productivity grew by just 1.4 percent, it was 3.3 percent among foreign firms.

Table 2: Summary of Covariates and Estimated Total Factor Productivity

Variables	Domestics Firms			Foreign Invested Firms			All Observations			Unit
	N	Mean	SD	N	Mean	SD	N	Mean	SD	
Value Added	156922	4815	64628	20035	35271	172258	176957	8264	84596	Million VND
Capital Stock	158145	8842	183939	20127	71070	341877	178272	15868	208799	Million VND
No. of Workers	163214	71	285	20255	452	1596	183469	113	606	Workers
Material Inputs	150924	25104	364197	18904	159615	779192	169828	40077	432717	Million VND
Log(TFP)	150301	8.344	2.017	19541	9.369	2.054	169842	8.462	2.048	
Growth in TFP	88,150	.014	.803	14398	.033	.822	102548	.017	.806	%

Notes: Authors' compilation and estimation using data drawn the Vietnam Enterprise Survey 2005–2010. Variables (except for estimated $\log(\text{TFP})$) are in nominal values.

For further investigation of the difference between foreign and domestic firms' total factor productivity distributions, Kernel densities of $\log(\text{TFP})$ by year and by firms' ownership are presented in Figure 4. The figure reveals that for all the years from 2005 through 2010 foreign firms' productivity distribution was consistently shifted towards the right tail, hence higher productivity levels, compared to their domestic counterparts. The mean in $\log(\text{TFP})$ (average over all years in Table 2) was also consistently higher in all years for foreign firms compared to domestic firms. While the mean of domestic firm's $\log(\text{TFP})$ is steadily increasing over time from 8.1 to 8.3, the foreign firms' productivity does not show a steady increase over time (not shown in the figure). This trend might indicate a TFP catch-up of domestic firm towards foreign firms in our study period. Figure 4 supports the notion that foreign firms are more productive so that technology and knowledge are more likely to spill over from foreign to domestic firms. In the following part, we explore the causal link between the temporal variation of the presence of foreign firms in proximity of domestic firms and domestic firms' subsequent TFP growth.

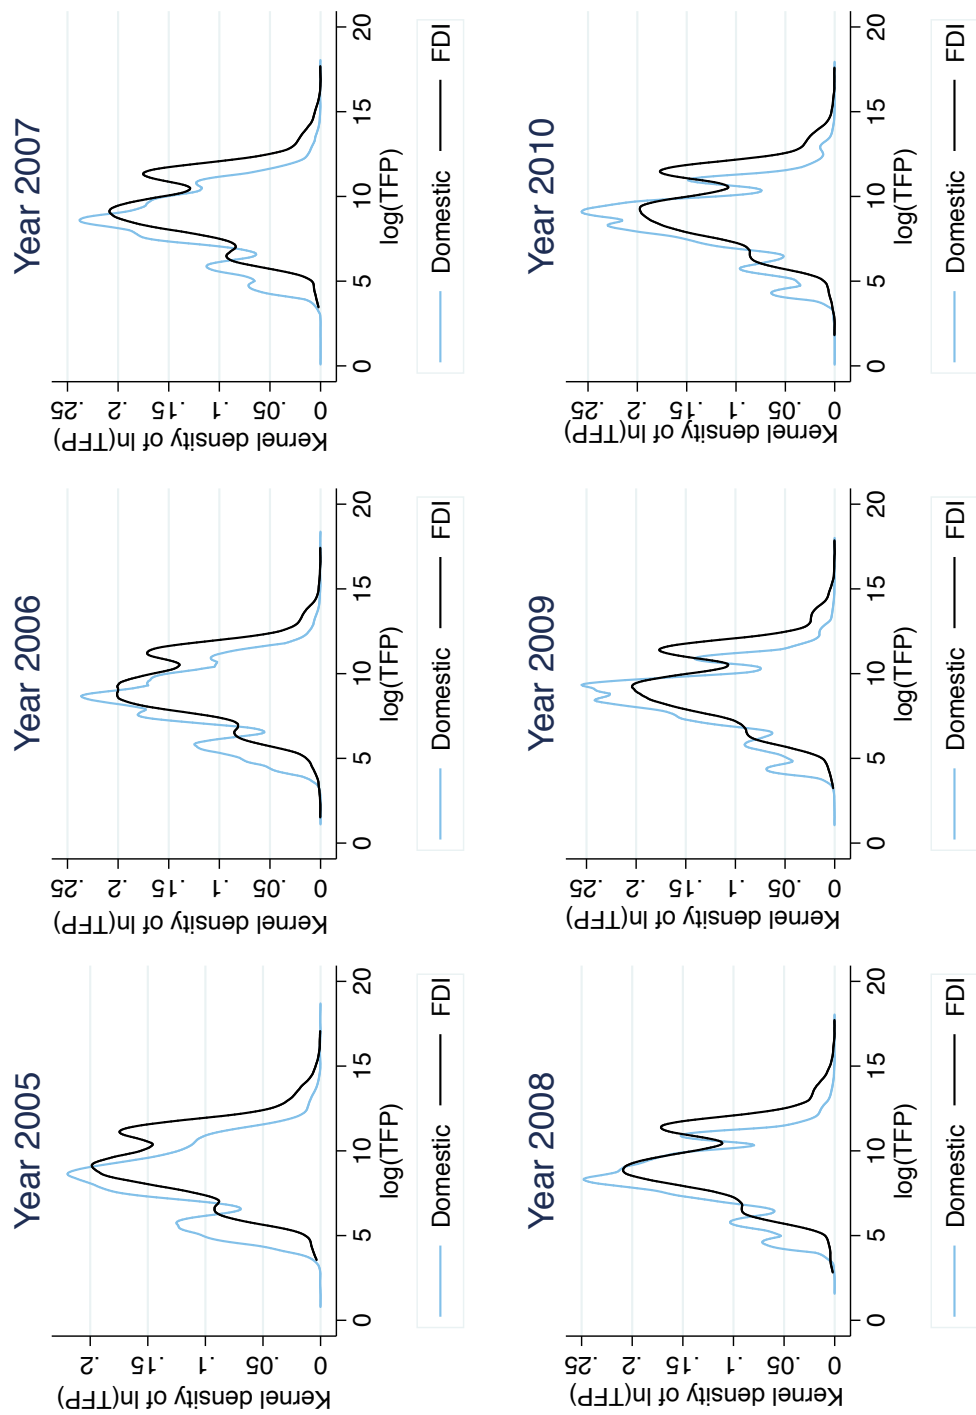

Figure 4: Kernel Distribution of Log(TFP) by Year and by Ownership

Notes: The figure displays a Kernel density estimator using a Epanechnikov Kernel function for foreign and domestic firms for each year. Log(TFP) is estimated by the methodology of Levinsohn and Petrin (2003) and based on data of the Vietnam Enterprise Survey, 2005–2010.

6 Localised FDI Spillover Effects: Identification Strategy and Results

In this section, we present our identification strategy for FDI spillover effects and the main results. The identification strategy isolates spillover effects of foreign investment on the local manufacturing firms. We apply a 2-stage-least-squares regression at the firm level utilising time variation in the presence of foreign investment in the near surrounding of each domestic firm, and control for possible confounders that may influence both the location of foreign investment and domestic firms' productivity growth. In section 6.2 we present a series of results focusing on within industry spillovers. We then disentangle the heterogeneity in effects according to firm size, productivity levels and the productivity gap of local firms to the foreign firms. Spillover effects working through the supply chain, called vertical linkages, are discussed in a separate section 6.6. Robustness checks confirm the main results.

6.1 Baseline Specification

Our baseline specification presents a causal estimation of the effect of foreign direct investment on total factor productivity growth of domestic firms in Vietnam. We presume that the influence of a foreign firm on a domestic firm is constraint to a geographic space around each local firm. We assess whether the change in presence of foreign invested firms within a specific perimeter of a domestic firm i in year t has a positive (or negative) spillover effect on the local firm's productivity. By varying the spatial extent of the radius around each firm – 2km, 5km, 10km, 20km, and 50km –, we investigate the intensity of spillovers with regard to geographical proximity. The inquiry of location specific spillovers effects restricted to a given radius around each firm i is similarly applied by e.g. Rosenthal and Strange (2008) on human capital spillovers in the US, Halpern and Muraközy (2007) on horizontal and vertical spillovers in Hungary, and Barrios et al. (2012) on R&D spillovers in Ireland.²³

The most simple assessment of within industry FDI spillover effects on productivity of domestic firms is to estimate the following specification by ordinary least squares:

$$\log(TFP_{ik,t}) = \alpha_i + \delta \log(FDI_{ik,t}^{RD}) + \beta \log(X_{ik,t}^{RD}) + \varphi HHI_{k,t} + \varepsilon_{ik,t} \quad (1)$$

where the dependent variable is the logarithm of $TFP_{ik,t}$ of domestic firm i in industry k at time t . The variable of interest is measuring the presence of foreign firms of the same industry k in a circle of radius RD around each domestic firm i , denominated $FDI_{ik,t}^{RD}$. We

²³Classifications of radii by Barrios et al. (2012) are 10km, 20km, 50km, 100km, 200km, and 300 km, respectively. In our study, the maximum radius for which we present results is 50km. Due to the peculiar shape of Vietnam, the support of the data gets unreliable beyond 50km.

measure the presence of foreign invested firms either by the number or the total output of firms within a circle. In order to interpret the estimated coefficient as elasticity of foreign direct investment on a local firm's productivity, we use the logarithm of $FDI_{ik,t}$. a_i is a firm fixed effect. $X_{ik,t}^{RD}$ is a vector of time varying control variables in logarithms measured for each firm within a circle of radius RD . It includes the local presence of domestic firms in the same industry k , the presence of foreign firms in all other industries, and the presence of domestic firms in all other industries. We hence control for all possible agglomeration economies and spillovers that are not attributable to foreign firms of the same industry. Furthermore, it also contains a variable that measures the size of the labor market, summing up the number of employees within the circle of radius RD . $HHI_{k,t}$ is an indicator for the concentration of an industry, the Herfindahl-Hirschman Index. $\varepsilon_{ik,t}$ is a an error term.

The above specification has one important caveat. According to Olley and Pakes (1996), total factor productivity follows the Markov rule: its current value depends on its past and hence forms an autocorrelation process. Therefore, a simple OLS estimation of the coefficients in the specification above omits one crucial variable, the lagged dependent variable (LDV) of total factor productivity.²⁴ In the existing literature on spillovers from foreign investment, this Markov process in total factor productivity is often ignored, as e.g. in Barrios et al. (2012) or Anwar and Nguyen (2014). Incorporating the LDV accounts for the AR(1) structure in the data generating process of dynamic total factor productivity at the firm level.

Including the LDV $\log(TFP_{ik,t-1})$ in a panel fixed effect estimation with a short time dimension yields, however, a downward bias (Nickell, 1981). By construction, the LDV correlates with the error term. In order to solve this estimation issue, we propose two steps following Anderson and Hsiao (1981). First, we estimate the specification in first differences, which eliminates the unobserved firm fixed effect. Moreover we can get rid of the persistent characteristic of the $\log(TFP)$ and reduce the problem of serial correlation. Second, we use $\ln(TFP_{ik,t-2})$ as an internal instrument for $\Delta \ln(TFP_{ik,t-1})$ and estimate the specification by 2-stage-least-squares.²⁵ Obviously, the following conditions need to hold to consistently estimate this instrumental variable approach:

$$E[\Delta \ln(TFP_{ik,t-1}) | \ln(TFP_{ik,t-2})] \neq 0 \quad (2)$$

and

²⁴E.g. Khandelwal and Topalova (2011) also raise similar concerns when estimating the impact of trade liberalisation on firm productivity.

²⁵Applying a GMM estimation and using additional lags as instruments would still increase efficiency. Our robustness checks show that results are very similar (to be done).

$$E[\Delta\varepsilon_{ik,t}|\ln(TFP_{ik,t-2})] = 0 \quad (3)$$

The enhanced specification in first differences, our baseline specification, hence is:

$$\begin{aligned} \Delta\log(TFP_{ik,t}) = & \rho\Delta\log(TFP_{ik,t-1}) + \delta\Delta\log(FDI_{ik,t}^{RD}) \\ & + \beta\Delta\log(X_{ik,t}^{RD}) + \varphi\Delta HHI_{k,t} \\ & + \Delta\phi_t + \Delta\eta_p \times \phi_t + \Delta\varepsilon_{ik,t} \end{aligned} \quad (4)$$

where we added time fixed effects, province fixed effects and time-province fixed effects. Industrial policy regulations are mostly determined at the national or provincial government level. By including province-time fixed effects $\rho \times \phi_t$, we take account of the regulatory environment that may change year on year, and regional business cycles. General annual shocks are absorbed by the time fixed effect ϕ_t . Naturally, to obtain a consistent estimation in equation 4, the control variables from the equation also need to be orthogonal to the error term $\Delta\varepsilon_{ik,t}$.

Our identification assumption with regard to the main regressor of interest $\Delta\log(FDI_{ik,t}^{RD})$ is that a single domestic firm is not decisive for the location choice of foreign invested firms. In other words, we assume that the yearly change of a single domestic firm's TFP is not affecting the change in foreign presence in the surrounding area of a firm. We argue that the problem of endogeneity is unlikely, since it is not possible for a foreign firm to observe the yearly change in a domestic firm's productivity (our dependent variable), and for that reason to select a specific location. Specifically, our assumption is that the change in productivity is only observed by the firm itself but not by other firms. When making investment decisions, foreign firms can investigate the general conditions of the location. The location choice first of all depends on local production conditions such as the local labour market, access to transportation infrastructure, and proximity to forward and backward linked industries. Further discussion about this issue is presented in Section 6.3.

Since there is no possibility to run a random experiment by assigning location choices to foreign firms and see how it affects TFP of domestic incumbent firms, we need to determine the factors that are correlated with the location choice of foreign firms and at the same time influence TFP of the domestic firms. By including likely confounding variables, we address these concerns. We control for the change in the presence of other domestic firms, foreign firms of all other industries, and the size of labor market. We are thus able to adjust our coefficient estimates for the attractiveness of a specific location for foreign investment. Furthermore, we present a placebo test in our baseline specification by including the lead of our variable measuring foreign investment within the close surrounding of domestic firms. If there was a selection problem in our specification, then change in productivity

should already be higher before foreign firms enter the location, hence show up in the lead, the year before foreign investment takes place. An additional potential confounding factor could be the development of local infrastructure that may both attract foreign investment and improve a local firm’s productivity. One may think of new roads or improved internet access that makes an area more attractive for investment. While the province time fixed effect should absorb large scale changes in accessibility, changes in local infrastructure is hard to capture. In order to dispel such concerns, we provide a variant of the basic specification using ward time fixed effects.

6.2 Baseline Results

This section presents the results of our estimation of local spillover effects of foreign direct investment on domestic firms’ productivity. The section is organised so as to cover various aspects of spillover effects discussed in the literature.

Table 3 presents our baseline estimations, by building up step by step our preferred specification. In these first series of regressions we consistently use the number of foreign firms in the vicinity of a domestic firm as underlying measure for our main explanatory variable. To construct it, we simply count the number of foreign firms of the same industry as the domestic firm within a circle of radius RD . Since we are estimating our specification in log differences, we can interpret this variable as growth rate in the presence of foreign firms within a certain area. We are convinced that the number of firms, while not containing any information on the size of firms, is a good indicator of the presence of foreign firms, because it is a rather neutral measure. A priori, one does not really know whether a few large firms convey more spillovers than a large number of small firms.

Panel A presents an ordinary least squares regression of the log of total factor productivity of domestic firms on the log of the number of foreign invested firms in the same industry in first differences, leaving aside any controls. Two important points are revealed. First, these raw results – while by first differencing is corrected for the unobserved firm fixed effect – show that there is a significant positive correlation between TFP growth of domestic firms and the change in the presence of foreign firms in the close surroundings of these domestic firms. Second, the relationship is strongest for circles with radii of 2 to 10 kilometres, and there seems also to be a clear decaying pattern of spillovers with increasing distance beyond 5 kilometres.

In panel B we add the control variables, accounting for agglomeration forces and factors influencing the location choice of foreign firms. The estimated coefficients slightly decrease in size, while keeping the decaying pattern and their significance. Panel C instruments the lagged dependent variable by the internal instrument $\ln(TFP_{ik,t-2})$. Estimated with a 2-stage-least-squares procedure it corresponds to the Anderson-Hsiao estimator (Anderson and Hsiao, 1981) and is our preferred specification.²⁶ The estimated coefficients are, again,

²⁶Adding further lags as instruments for the lagged dependent variable in differences in a GMM frame-

Notes: Dependent Variable is annual TFP growth, defined as $\log(TFP_{ik,t}) - \log(TFP_{ik,t-1})$. Our main explanatory variable is $\Delta \log$ No. of FDI firms, defined as the annual change of the log of number of foreign invested firms within a circle of radius RD . Estimations include a lagged dependent variable $\Delta \log(TFP_{i,t-1})$ that is instrumented with its lagged value in levels $\log(TFP_{ik,t-2})$. The control variables (Panels B, C, and D) are measured for each firm within a circle of radius RD over time, and calculated as annual change in logarithms. They include the number of domestic firms in the same industry k , the number of foreign firms in all other manufacturing industries, the number of domestic firms in all other manufacturing industries, and the labor force (total number of workers) of all manufacturing industries. Further included is the annual change of the Herfindahl-Index at the industry level. All estimations include time fixed effects, province-time fixed effects, and industry fixed effects. Huber-White standard errors in parentheses are clustered at the industry level. + $p < 0.10$, * $p < 0.05$, ** $p < 0.01$ *** $p < 0.001$.

highly significant and still show the pattern of strong within industry localised spillover effects, and the weakening of spillovers beyond 5 to 10 kilometres. The coefficients are only significantly different from zero up to a circle with a radius 20 kilometres. While the

work would increase efficiency. However, due to the unbalanced structure of our data, adding further lags results in losing numerous observations. Since our first stage estimation confirms the strength of the instrument, we stick with the simple version with only one lag. We checked the results using GMM, but the loss in observations due to using additional lags is actually worse than the increase in efficiency. Results are available on request.

effect within a circle of 5 kilometres is substantial at almost 0.3 percentage points higher growth in TFP by an additional percent in the number of foreign firms.

Panel C additionally presents the results for the four most relevant control variables. Remarkably, foreign invested firms other than those of the same industry do not have positive impact on the local economy. In contrast, having more foreign firms close by does have a significantly negative impact on TFP growth of domestic firms. Yet the effect is much smaller and is more than compensated by the positive effect of within industry foreign investment. This interesting results proposes that foreign firms absorb resources when settling into an area. In case the foreign firm is from a different industry there are no positive spillovers and only the negative impact on domestic firms' TFP remains. Other domestic firms do not show spillover effects, both within and across industries. Although we should be able to detect agglomeration spillovers, this restrictive estimation seems to absorb them.

The lagged dependent variable $\Delta \log(TFP_{i,t-1})$ is strongly affecting current TFP growth, supporting our concern of a dynamic autocorrelation process in our dependent variable. The high value of the first stage F-test suggests that the internal instrument is working well.

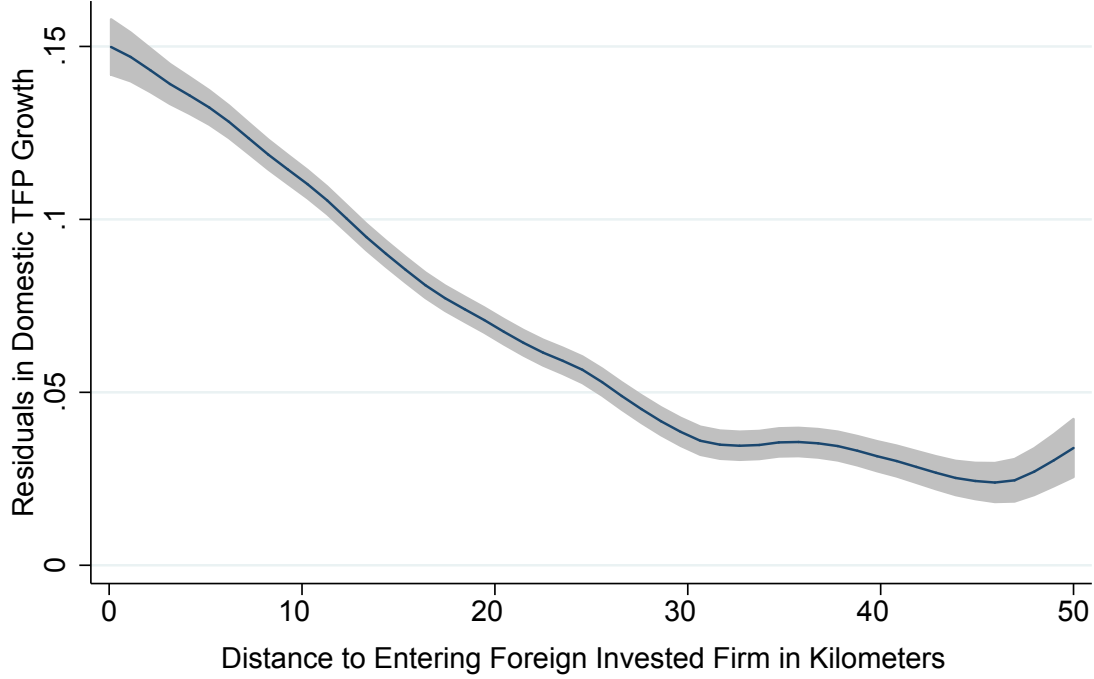

Panel D presents a placebo test. Instead of the contemporaneous value of FDI, its lead $\Delta \log(NOF TFP_{ik,t+1})$ is included as main regressor. There seems to be no selection problem in the sense that foreign firms move to places where TFP growth of domestic firms is high in the previous year. This placebo test affirms our well specified estimation procedure.

To illustrate the pattern of spillover effects, Figure 5 depicts a local polynomial regression of the residual in TFP growth of domestic firms on their distance to entering foreign invested firms. The residual is based on a regression of TFP growth on industry fixed effects, interaction between time and province dummies, and time fixed effects in order to account for the location specific factors that influence TFP growth. The figure impressively depicts the spillover effects that attenuate with increasing distance. It resembles our baseline results in Table 3. The decay in spillovers is very regular and approaches zero at larger distances beyond 30 kilometres.

Table 4 presents the exactly same series of regressions, though using total revenue of foreign firms as the underlying measurement of foreign direct investment. The overall pattern in the results is highly similar. However, estimated spillover effects are weaker and limited to a circle size of radius 5 kilometres. A one percent increase in the change of presence of foreign firms measured by their revenue within a 5 kilometre radius translates into an increase in TFP growth of 0.015 percentage points.

Drawing a preliminary conclusion from our main results, within industry or horizontal spillover effects of foreign direct invested firms seem to be a distinctly local phenomenon. They only occur within limited spatial scope, quickly fading out beyond 5 to 10 kilome-

Figure 5: Entering Foreign Invested Firms and Domestic TFP Growth

Notes: The figure presents a kernel-weighted local polynomial regression of domestic firm level TFP growth on the distance to entering foreign invested firms. In gray is a 95% level confidence band. Each observation in the regression is a domestic firm–foreign firm dyad. The residual is based on a regression of TFP growth on industry fixed effects, time–province fixed effects, and time fixed effects. The local polynomial uses an Epanechnikov kernel of degree 0, a bandwidth of 2.96, and pilot bandwidth for calculating the standard errors of 4.44.

tres. These results may suggest why most studies that analyse within industry foreign investment spillovers do not find significant results, as e.g. Newman et al., 2015 for the case of Vietnam: their data simply does not allow them to detect such localised horizontal spillover effects.

6.3 Does Domestic Firm Size Matter for Spillover Effects?

In this subsection we provide more evidence on the heterogeneity of effects with respect to firm size of local establishments. Table 5 presents the results with regard to size of domestic firms measured by the number of workers. The regressions are also based on our baseline specification in first differences and instrumenting the lagged dependent variable. The whole sample of domestic firms is divided into three brackets according to the definition of firm size by the Vietnamese Statistical Office: micro firms with up to 10 workers, small firms have between 10 and 200 workers, and medium and large firms have more than 200 workers.²⁷

Remarkably, micro firms seem to especially benefit from the presence of foreign firms in close proximity: Firms with less than 10 employees exhibit the largest coefficients at 0.4 percentage points additional growth in TFP as they are exposed to an additional one

²⁷Spillover effects for medium and large firms are jointly estimated since the sample becomes small.

Notes: Dependent Variable is annual TFP growth, defined as $\log(TFP_{ik,t}) - \log(TFP_{ik,t-1})$. Our main explanatory variable is $\Delta \text{Log Tot. Rev. of FDI firms}$, defined as the annual change of the log of the total revenue of foreign invested firms within a circle of radius RD . Estimations include a lagged dependent variable $\Delta \text{Log}(TFP_{i,t-1})$ that is instrumented with its lagged value in levels $\log(TFP_{ik,t-2})$. The control variables (Panels B, C, and D) are measured for each firm within a circle of radius RD over time, and calculated as annual change in logarithms. They include the sum of total revenue of all other domestic firms in the same industry k , the sum of total revenue of foreign firms in all other manufacturing industries, the sum of total revenue of domestic firms in all other manufacturing industries, and the labor force (total number of workers) of all manufacturing industries. Further included is the annual change of the Herfindahl-Index at the industry level. All estimations include year fixed effects, province-year fixed effects, and industry fixed effects. Huber-White standard errors in parentheses are clustered at the industry level. + $p < 0.10$, * $p < 0.05$, ** $p < 0.01$ *** $p < 0.001$.

percent of foreign firms within 5 kilometres (panel A). Again, one observes a distinct decay of spillovers beyond a 5 kilometre radius. In panel B, the effects are similar although somewhat smaller for firms with 11 to 200 workers employed. For this group of small firms, spillover effects are strongest within 10 kilometres, restricted to a circle radius of 20 kilometres, and they fade out with increasing distance.

The group of medium and large firms is the smallest bracket as there are about 6'000 such firms in our sample. Also for the medium and large firms, the pattern of spillover effects is localised, affirming the robustness in spillover pattern. The effects are slightly increasing up to 10 kilometres, and fading out thereafter. Yet, the effect is only significant within a distance of 5 kilometres, at the 10 percent level. The estimated size of the spillover effect appears to be smaller for these large firms than for the small firms.²⁸

Notes: Dependent Variable is annual TFP growth, defined as $\log(TFP_{ik,t}) - \log(TFP_{ik,t-1})$. Our main explanatory variable is $\Delta \text{Log No. of FDI firms within industry}$, defined as the annual change of the log of number of foreign invested firms in the same industry within a circle of radius RD . Estimations include a lagged dependent variable $\Delta \log(TFP_{ik,t-1})$ that is instrumented with its lagged value in levels $\log(TFP_{ik,t-2})$. The control variables are measured for each firm within a circle of radius RD over time, and calculated as annual change in logarithms. They include the local number of domestic firms in the same industry k , the number of foreign firms in all other manufacturing industries, the number of domestic firms in all other manufacturing industries, and the labor force (total number of workers) of all manufacturing industries. Further included is the annual change of the Herfindahl-Index at the industry level. All estimations include time fixed effects, province-time fixed effects, and industry fixed effects. Huber-White standard errors in parentheses are clustered at the industry level. + $p < 0.10$, * $p < 0.05$, ** $p < 0.01$ *** $p < 0.001$.

To figure out whether this larger effects for small firms actually leads to an absolute convergence in productivity of small and large firms, it is insightful to have a closer look at the size of effects over time. The average TFP level for micro firms is around 2'600

²⁸A direct comparison of effects is not possible based on these results since the table presents an separate estimation for each subsample.

in the year 2006, while the average for small firms with 11 to 200 workers is 4'300. The average TFP of medium and large firms was 15'700 in 2006. An additional 10 percent in the presence of foreign firms would increase TFP growth for micro firms by 4.1 percentage points, which would yield a TFP level of 3'183 after five years, and hence an absolute gain of 580. For a small firm, the same increase in the presence of foreign firms would yield a TFP level of 5'345. The gain in TFP is 632 and slightly larger in absolute terms after 5 years. We hence cannot expect a closing gap in productivity between micro and small firms due to the presence of foreign firms within 5 kilometres in the medium term. For medium and large firms, a 10 percent increase in the presence of foreign firms would lead to an additional TFP of 1'578, an absolute increase higher than the gain for micro and small firms. We hence conclude that the presence of foreign firms in the close surroundings of domestic firms does not lead to an absolute convergence process in TFP levels between micro, small and large firms in the medium run of 5 years

Overall, the analysis of spillover effects for different domestic firm sizes reveals that micro and small firms appear to benefit from foreign investment even more than medium and large firms in relative terms. The within industry spillover effects are restricted to a small distances, both for large and small firms.

6.4 Does the Productivity Level of Domestic Firms Matter for Spillovers Effects?

In this section we look at the heterogeneity in effects with respect to productivity levels of domestic firms within each industry. For each industry, we divide the sample of firms into three groups: below median productivity, third quartile of productivity, and fourth quartile of productivity.²⁹

The results in Table 6 are astounding. Relatively unproductive firms within each industry seem to specifically benefit from the presence of foreign firms in their vicinity (panel A). Firms at the upper end of the productivity distribution, in contrast, show less pronounced signs of spillover effects. Yet the pattern of decaying spillovers is still detectable (panel C). Domestic firms in the third quartile of the TFP distribution also experience large and significant spillover effects, which are yet somewhat smaller (panel B). These results indicate a convergence process in productivity levels between low and high productivity firms. Unproductive firms indeed seem to be able to absorb know-how from their foreign counterparts, but only if they are sufficiently close-by.³⁰

While one would need to look at each industry individually to see if there is absolute convergence in productivity levels, we can still make some calculation at the average of

²⁹Instead of dividing the group into three equally large groups, we decided to separate the unproductive lower half of firms from the third and fourth quartile. It seems more interesting to have a more pronounced picture in the upper half of the productivity distribution.

³⁰A direct comparison of effects is not possible based on these results since the table presents an separate estimation for each subsample.

Table 6: Spillover Effects for Unproductive and Productive Domestic Firms, 2SLS estimation

Notes: Dependent Variable is annual TFP growth, defined as $\log(TFP_{ik,t}) - \log(TFP_{ik,t-1})$. Our main explanatory variable is $\Delta \text{Log No. of FDI firms}$, defined as the annual change of the log of number of foreign invested firms within a circle of radius RD . Estimations include a lagged dependent variable $\Delta \log(TFP_{i,t-1})$ that is instrumented with its lagged value in levels $\log(TFP_{ik,t-2})$. The control variables are measured for each firm within a circle of radius RD over time, and calculated as annual change in logarithms. They include the local number of domestic firms in the same industry k , the number of foreign firms in all other manufacturing industries, the number of domestic firms in all other manufacturing industries, and the labor force (total number of workers) of all manufacturing industries. Further included is the annual change of the Herfindahl-Index at the industry level. All estimations include year fixed effects, province-year fixed effects, and industry fixed effects. Huber-White standard errors in parentheses are clustered at the industry level. + $p < 0.10$, * $p < 0.05$, ** $p < 0.01$ *** $p < 0.001$.

each group of firms. A 10 percent increase in the presence of foreign firms would lead to an absolute growth of TFP of 604 for low productivity firms, 610 for medium productive firms, and 812 for the productive firms over a 5 year period. While, at first glance, these back of the envelope calculations do not point to a quick convergence of productivity levels, unproductive and medium productive firms may increase their productivity almost at the same rate. Furthermore, while the effects for the productive quartile of firms is large in absolute terms, the effects are only marginally significant.

6.5 Does the Productivity Gap between Domestic and Foreign Firms Matter?

In this section, we specifically look at how the productivity level of foreign firms is affecting domestic firms' productivity of diverse productivity levels. Do domestic firms benefit more from foreign firms of similar productivity levels or from foreign firms of much higher productivity? To answer this question, we divide the sample into groups of firms according to their TFP level for each industry. We define three groups: below median (low productiv-

ity), third quartile (medium productivity), and fourth quartile (high productivity). Both domestic firms and foreign firms are divided under the same TFP distribution for each industry. Since we want to look at the productivity gap within a certain circle of radius RD , we cannot directly calculate a TFP gap to the foreign productivity leader since in many cases, there are no foreign firms within a certain radius at all. The objective of this analysis is to figure out whether the technology gap is important in determining the size of spillover effects.

We perform a series of our baseline regression while including only certain subsamples with specific TFP levels. Figure 6 depicts 3x3 graphs with combinations of TFP levels of foreign and domestic firms. The top row shows low productivity domestic firms, while the TFP level of foreign firms increases from left to right: lower half, third quartile, and fourth quartile. The middle row shows domestic firms with medium level (third quartile) TFP, while, again, varying the level of foreign firms' level of TFP. And logically, the third row shows high productivity domestic firms, with increasing levels of foreign firms' productivity level from left to right.

Two results stand out. First, unproductive local firms (row 1) seem to benefit both from rather unproductive foreign firms, but also from very productive firms. Firms are able to learn both from other firms in the same industry that are similar in technology levels, but even more so from firms that are at a advanced technology level. The size in spillover effects is smallest for foreign firms with intermediate productivity levels (middle column). The patterns is similar for medium (row 2) and highly productive (row 3) domestic firms, although with reduced clarity. The productive domestic firms absorb the smallest spillover effects overall, and less significantly so. Second, and more importantly, a small productivity gap leads to a relatively lower learning ability of domestic firms, compared to a large productivity gap. A larger productivity gap between foreign and domestic firms within the same industry appears to facilitate the learning aptitude of domestic firms.

What is common to all combinations of productivity levels of domestic and foreign firms is the diminishing pattern of spillover effects with increasing distance. This, again, supports the robustness of the pattern in our baseline results. A further investigation of the productivity gap could reveal a more clear picture of effects, yet this is beyond the scope of this paper.

6.6 Localised Spillover Effects Through Vertical Linkages (Manufacturing and Services): Specification and Results

Vertical linkages between foreign and domestic firms to upstream (forward linked) and downstream (backward linked) industries are another important channel through which spillover effects may work. With regard to FDI presence in vertical linkages, spillover effects have been extensively studied by various scholars (see e.g. Javorcik, 2004, Halpern

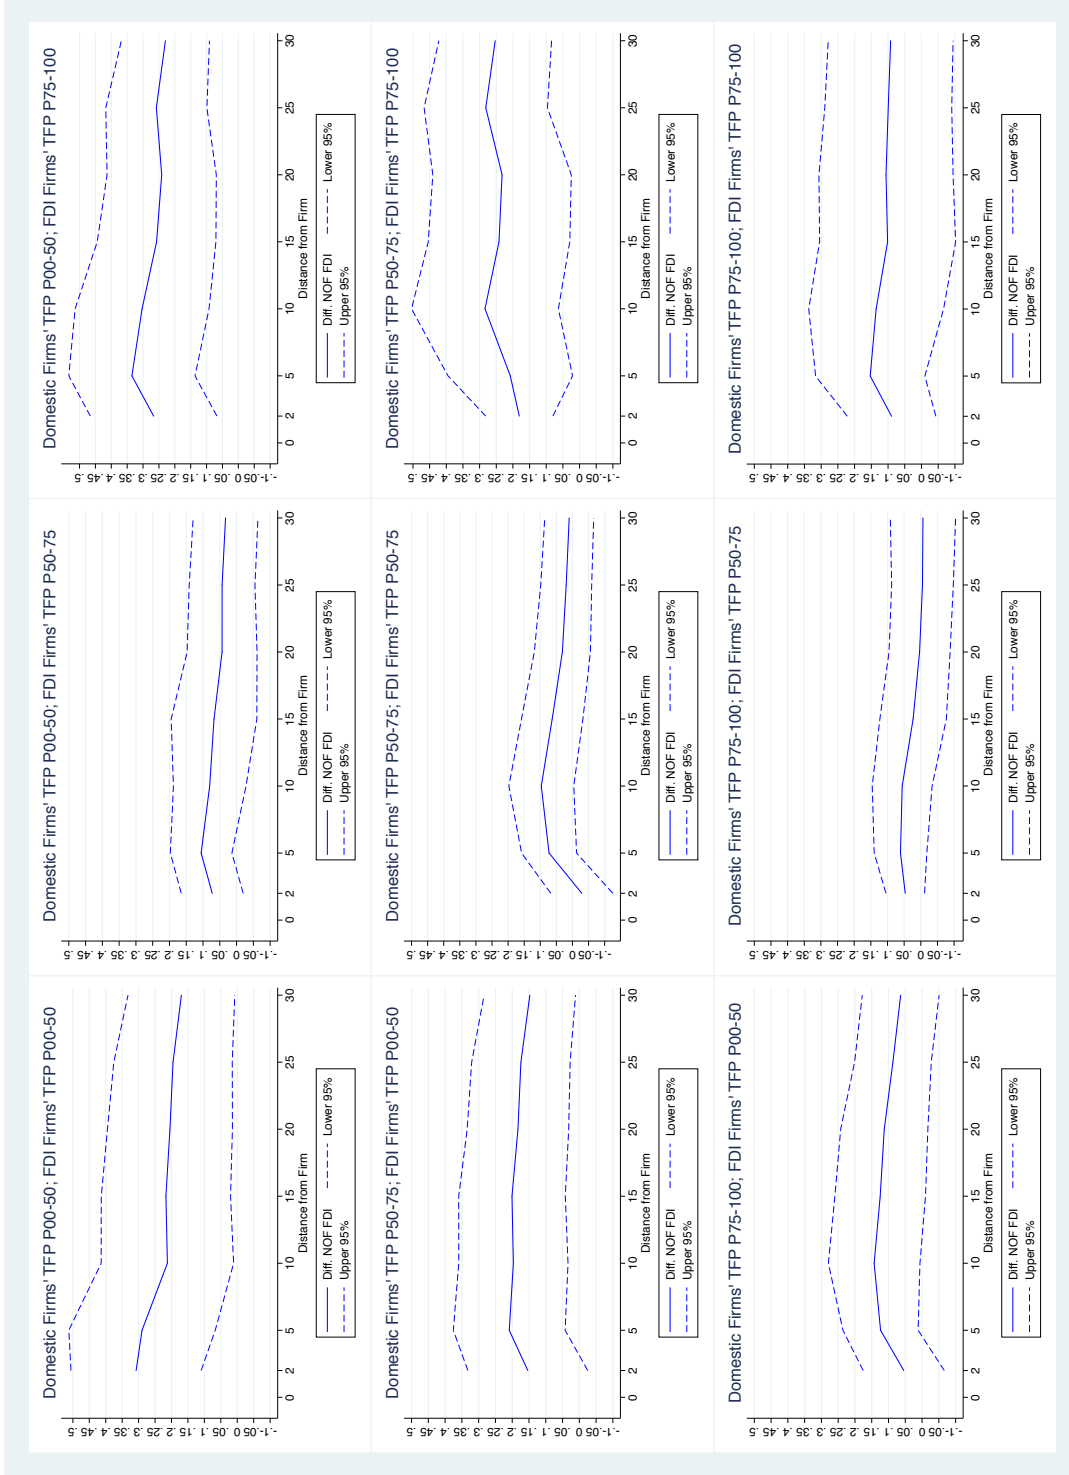

Figure 6: Varying Productivity of Foreign Firms Affecting Low and High Productivity Domestic Firms

Notes: The 9 graphs show our baseline regressions of growth in TFP on growth of number of foreign firms within a circle. Each graph shows a distinct combination of TFP levels of domestic and foreign firms. "Domestic firms' TFP P00-50" means the firm the estimation was based on a sample selection of domestic firms with TFP level below the median. TFP P50-75 is the third quartile of TFP levels, and P75-100 is the fourth quartile TFP level of all firms. Denotation for TFP levels of foreign firms is identical. The TFP quartiles are based on the whole sample of domestic and foreign firms.

and Muraközy, 2007, Anwar, 2011, and Newman et al., 2015). In the following, we assess the relevance of foreign presence in forward and backward linkages, yet in our established spatial framework, by adding these linkages to our baseline regression. Instead of just considering vertical linkages within an industry as done in most existing studies, we investigate vertical linkages to FDI firms in the vicinity of each domestic firms. Due to the decentralised structure of our data, we calculate the absolute value of deflated revenue produced by foreign firms in forward and backward linked industries instead of the output share (Javorcik, 2004) or value added share (Francois and Woerz, 2008). We enhance our baseline specification with the vertical forward and backward linkages as follows:

$$\begin{aligned}
\Delta \log(TFP_{ik,t}) = & \rho \Delta \log(TFP_{ik,t-1}) + \delta \Delta \log(FDI_{ik,t}^{RD}) \\
& + \kappa_1 \Delta \log(FWL \text{ Manu}_{i,fk,t}^{RD}) + \kappa_2 \Delta \log(BWL \text{ Manu}_{i,kb,t}^{RD}) \\
& + \kappa_3 \Delta \log(FWL \text{ Serv}_{i,fk,t}^{RD}) + \kappa_4 \Delta \log(BWL \text{ Serv}_{i,kb,t}^{RD}) \\
& + \lambda \Delta \log(DOM \text{ Links}_{ik,t}^{RD}) + \beta \Delta \log(X_{ik,t}^{RD}) + \varphi \Delta HHI_{k,t} \\
& + \Delta \phi_t + \Delta \eta_p * \phi_t + \Delta \varepsilon_{ik,t}
\end{aligned} \tag{5}$$

where we construct the four variables measuring vertical linkages to foreign firms as follows. The first differenced vertical linkage to foreign invested manufacturing firms in forward linked industries is defined as

$$\Delta \log(FWL \text{ Manu}_{i,fk,t}^{RD}) = \log\left(\sum_{j=1}^N \alpha_{fk} TR_{jf,t}^{RD}\right) - \log\left(\sum_{j=1}^N \alpha_{fk} TR_{jf,t-1}^{RD}\right) \tag{6}$$

reflecting the annual change in the forward linked foreign manufacturing firms in industries f within a circle of radius RD around each domestic firm i . Each dyad foreign firm j 's total revenue TR is weighted by α_{fk} , the coefficient measuring the forward link in the input-output table. α_{fk} measures the amount of goods supplied by forward linked industries f (upstream) to downstream industries k .³¹

The first differenced vertical linkage to foreign invested manufacturing firms in backward linked industries is defined as

$$\Delta \log(BWL \text{ Manu}_{i,kb,t}^{RD}) = \log\left(\sum_{i=1}^N \beta_{kb} TR_{ib,t}^{RD}\right) - \log\left(\sum_{i=1}^N \beta_{kb} TR_{ib,t-1}^{RD}\right) \tag{7}$$

³¹The indices reflect three types of industries: k is the industry of domestic firm i itself. Industries f are forward linked industries (upstream), and industries b are backward linked industries. The index fk represents goods or services supplied by industry f to industry k ; kb represents goods or services supplied by industry k to industry b . As mentioned before, we use the same definition of forward and backward linkages as Newman et al. (2015): forward linkages are upstream foreign suppliers; backward linkages are downstream foreign customers. This definition of forward and backward is implicitly referring to the perspective of the foreign firm.

where total revenue $TR_{jb,t}$ of each downstream foreign firms j is weighted by β_{kb} , measuring the amount of goods supplied by upstream industry k to downstream industry b .

The remaining two linkages to forward and backward linked service firms are calculated identically as:

$$\Delta \log(FWL\ Serv_{i,fk,t}^{RD}) = \log\left(\sum_{i=1}^N \alpha_{fk} TR_{jf,t}^{RD}\right) - \log\left(\sum_{i=1}^N \alpha_{fk} TR_{jf,t-1}^{RD}\right) \quad (8)$$

$$\Delta \log(BWL\ Serv_{i,kb,t}^{RD}) = \log\left(\sum_{i=1}^N \beta_{kb} TR_{jb,t}^{RD}\right) - \log\left(\sum_{i=1}^N \beta_{kb} TR_{jb,t-1}^{RD}\right) \quad (9)$$

Specification 5 also includes a set of control variables $\Delta \log(DOM\ Links_{ik,t}^{RD})$, measuring the presence of forward and backward linked domestic firms. Identically as for the vertical links, we calculate these four types of vertical links for domestic firms.

Table 7 presents the results of our baseline specification, but now including the four variables measuring the vertical linkages to forward and backward linked foreign firms, as described above. In general, spillover effects, whether positive or negative, seem to be much more locally restricted in the manufacturing sector compared to the service sector. The coefficients on the measures of linkages to foreign firms in manufacturing sectors are only significant within 10 kilometres. This result confirms the spatially bounded spillover effects among manufacturing industries and is robust for horizontal and vertical linkages. Besides, spillover effects from foreign service firms are quite stable across space and significant also across larger distances.

Our preferred 2SLS estimates are presented in Panel C in Table 7, including the horizontal linkages from our baseline regression and all control variables. Regarding vertical linkages from FDI manufacturers, our estimations show positive spillover effects from forward linked industries (i.e. foreign manufacturing firms are suppliers to domestic firms). The spillover effects are spatially restricted to within 10 kilometres. This finding is partly in line with the results of Newman et al. (2015) who also find positive spillovers from FDI forward linkages for Vietnamese manufacturing during the period 2006 to 2012 (the research period is comparable to ours), but only when they consider direct forward linkages of upstream foreign to downstream domestic producers.³² The positive spillovers from upstream foreign firms may be explained by the know-how transfer through the products supplied to domestic downstream firms.

Spillover effects from backward linked foreign firms are negative (foreign manufacturing

³²Newman et al. (2015) distinguish between direct and indirect vertical linkages. As they have information on direct supplier-customer relationships, they are able to measure direct links between firms, although for a much smaller sample. We construct the vertical linkages by the input-output table and cannot distinguish between direct and indirect linkages. As we look at vertical linkages in close proximity of domestic firms, the probability that a vertical linkage is actually a supplier-customer relationship is increasing, if we assume that closer firms are more likely to trade.

firms as customers of domestic firms). The foreign firms in downstream industries might have substantial bargaining power and drive down sale prices for domestic firms. As foreign firms in downstream sectors enter the market and choose locations close to the domestic firms, they also potentially absorb a lot of resources, as e.g. high skilled employees join technologically more advanced foreign firms in downstream industries. This result is, however, in contrast to the literature: Tran and Pham (2013), for instance, find positive backward and negative forward spillovers in their case study of FDI spillovers in the Vietnamese manufacturing sectors for the period 2000 to 2005. Our results are, however, not fully comparable to other studies as we analyse the vertical linkages in our spatial framework, where different mechanisms are supposedly at play.

Interestingly, spillovers through vertical linkages of foreign service companies seem much less spatially constraint.³³ Our results record negative spillover effects from forward service linkages, and positive spillover effects for backward linked foreign service firms. Both effects do not provide evidence that spillover effects through vertical service linkages do fade out with increasing distance. This finding is not in line with results in the literature which indicate evidence of positive impacts from foreign service suppliers on the performance of downstream manufacturing (e.g. Francois and Hoekman, 2010). Arnold, Javorcik and Mattoo (2011) find a positive correlation between liberalisation in the service sector and the productivity of downstream manufacturing firms.

Again, our results are not easily comparable to the results in the literature as we look specifically at the presence of foreign firms in vertical linkages within a certain area. The interpretation of our results is, therefore, different from most studies. Most importantly, however, is the fact that the horizontal spillovers are stable and keep being significant after controlling for vertical linkages in panel C of Table 7. This supports the robustness of our results on the spatially restricted horizontal spillover effects of foreign direct investment.

³³This is in contrast to the findings of Hilber and Voicu (2010) who state service agglomeration economies to be localised. However, Hilber and Voicu (2010) include both domestic and foreign service suppliers.

7 Conclusion

This paper investigates spillover effects of foreign direct investment on the local economy with specific focus on the role of proximity between foreign and local firms. A unique data set with detailed geo-referenced firm data allows us go one step beyond existing studies conducted at the regional level. We provide a spatially precise analysis of FDI spillover effects using a large sample of Vietnamese manufacturing firms over the period 2005 to 2010. Exploiting variation in the presence of foreign firms in the vicinity of local establishments, we contribute interesting new evidence of remarkably localised foreign investment spillover effects to the literature.

We find positive and highly significant within industry (horizontal) spillover effects of a highly localised type. Spillovers are strongest within distances of 2 to 10 kilometres and fade out beyond. Our 2-stage least squares estimations, accounting for the dynamics in TFP, estimate elasticities of 0.25–0.4 in TFP growth with respect to changes in FDI presence in the surrounding of domestic firms within a distance of 10 kilometres. Analysing the presence of foreign firms in terms of revenue, elasticities of TFP growth with respect to foreign investment is about 0.017 within a five kilometre radius. These results reflect studies in the agglomeration literature that emphasise the very localised characteristics of agglomeration externalities (e.g. Rosenthal and Strange, 2003). This main result is robust to a variety of concerns. Placebo tests show that our specification is able to control for possible local selection effects of foreign investment. Results are also stable both in the northern and southern regions of Vietnam, and even when ward-time fixed effects are included.

Furthermore, our results indicate that spillover effects are in fact largest for small and relatively unproductive firms. Estimated elasticities are larger and more significant for micro and small firms with a labor force of up to 200 workers. The lower half of firms in terms of industry productivity benefit more than the more productive half. Notably, our results also show that vertical spillovers from foreign manufacturing firms are localised while the spillovers from foreign service firms are not spatially constraint.

Notes: Dependent Variable is annual TFP growth, defined as $\log(TFP_{ik,t}) - \log(TFP_{ik,t-1})$. Our main explanatory variables are measuring the presence of foreign firms in forward and backward linked manufacturing and service sectors within a circle of radius RD around a domestic firm. The linkages are calculated as the weighted sum of total revenue of foreign firms in forward and backward linked industries within a circle of radius RD , and are calculated as annual changes in logarithms. The weights are α_{jk} , measuring the supply goods of forward linked industry j to industry k of the domestic firm i , and β_{kj} measuring the supply of goods of industry k of domestic firm i to backward linked industry j . Also included is the horizontal linkage $\Delta \log \text{Tot. Rev. of FDI firms}$, defined as the annual change of the log of the total revenue of foreign invested firms in industry k within a circle of radius RD . 2SLS estimations include a lagged dependent variable $\Delta \log(TFP_{i,t-1})$ that is instrumented with its lagged value in levels $\log(TFP_{ik,t-2})$. The control variables are measured for each firm within a circle of radius RD over time, and calculated as annual change in logarithms. They include the sum of total revenue of all other domestic firms in the same industry k , the sum of total revenue of foreign firms in all other manufacturing industries, the sum of total revenue of domestic firms in all other manufacturing industries, and the labor force (total number of workers) of all manufacturing industries. Further included is the annual change of the Herfindahl-Index at the industry level. All estimations include year fixed effects, province-year fixed effects, and industry fixed effects. Huber-White standard errors in parentheses are clustered at the industry level. + $p < 0.10$, * $p < 0.05$, ** $p < 0.01$ *** $p < 0.001$.

A Total Factor Productivity Estimation Appendix

As noted by Olley and Pakes (1996), coefficients of capital stocks estimated in the Cobb-Douglas production function by simply using OLS are biased upwards due to the correlation between capital stock and unobserved productivity shocks (TFP). In addition, the authors also indicate that using balanced panel data to estimate TFP, which ignores the entry and exit of firms in the industries, causes a selection bias problem. They argue that the efficient firm, which maximises its “expected discounted value of future net cash flow” in a framework of the Bellman equation, stays in the industry and invests more if its TFP level exceeds a certain threshold. A less efficient firm that has a TFP level below the threshold in contrast, exits the market (Olley and Pakes, 1996).

Olley and Pakes (1996) solve for the selection bias and simultaneity issues in dynamic TFP estimation by using unbalanced panel data and including the survival ratio of a firm in the industry in their estimation. Importantly, they use investment as the proxy for unobserved productivity. They argue that there is a correlation between the choice of the capital stock, investment demand and TFP. Capital stocks are determined at period $t - 1$ such that:

$$K_{i,t} = (1 - \delta)(K_{i,t-1}) + I_{i,t-1} \quad (\text{A.1})$$

Where δ is the depreciation ratio, $K_{i,t}$ and $K_{i,t-1}$ are respectively the capital stocks in year t and year $t - 1$, and $I_{i,t-1}$ is the investment of firm i in year $t - 1$.

The investment demand is assumed to be monotonically increasing in TFP. Thus, the demand function of investment can be inverted and investment can be used as proxy for the productivity shock ω . The investment demand is defined as

$$I_t = f_t(K_t, \omega_t) \quad (\text{A.2})$$

With the assumption that $I_t > 0$, after being inverted, we get

$$\omega_t = f_t^{-1}(I_t, K_t) \quad (\text{A.3})$$

Due to the possibility of non-availability or negative values of investment reported in many data sets, Levinsohn and Petrin (2003) develop a theoretical framework based on Olley and Pakes (1996) and suggest to use intermediate inputs as alternative proxies for unobserved productivity shocks instead of investment. Important assumptions made by Olley and Pakes (1996) are kept in Levinsohn’s (2003) model. Moreover, the demand of intermediate inputs chosen needs to be strictly increasing in productivity.

The Cobb-Douglas production function is assumed to be similar among firms in the same industry.

$$VA_{it} = A_{it}K_{it}^{\beta_k}L_{it}^{\beta_l} \quad (\text{A.4})$$

Taking logarithms of both sides we have

$$\log(VA_{it}) = \beta_0 + \beta_k \log(K_{it}) + \beta_l \log(L_{it}) + \omega_{it} + \varepsilon_{it} \quad (\text{A.5})$$

In equation (A.5), $\log(VA_{it})$ is the logarithm of deflated value added, while $\log(L_{it})$ is the logarithm of number of labourers, and $\log(K_{it})$ is the logarithm of the real capital stock.³⁴ ω_{it} is the productivity shock (TFP) we need to estimate. ε_{it} is the error term that is unknown to the firm and the econometrician. ω_{it} is known by the firm when it makes the choice on intermediate inputs and the capital stock, but it is also unobserved by the econometricians.

Rewriting equation (A.5) in lower case, we have

$$va_{it} = \beta_0 + \beta_k k_{it} + \beta_l l_{it} + \omega_{it} + \varepsilon_{it} \quad (\text{A.6})$$

The assumptions implied in equation (A.6) follow Levinsohn and Petrin (2003) and Petrin, Poi and Levinsohn (2004), such that

- (i) The choice of intermediate input m_{it} response to k_{it} and ω_{it} :

$$m_{it} = m(k_{it}, \omega_{it})$$

When a firm gains higher productivity than the threshold and stays in the market, it expands the demand for intermediate inputs, so $m_{it} > 0$, which allows for $m_{it}(k_{it}, \omega_{it})$ to be inverted. Therefore $\omega_{it} = \omega(k_{it}, m_{it})$.

- (ii) Labour is not a state variable which means it is demanded when the productivity is realised. In this case, we choose the number of employees as labor input, as we do not have information on the wage or working hours.³⁵

- (iii) The first-order Markov process is applied to productivity shocks:

$$\omega_{it} = E[\omega_{i,t} | \omega_{i,t-1}] + \xi_{i,t} \quad (\text{A.7})$$

where $\xi_{i,t}$ is the innovation to productivity.

³⁴The Value added production function is popularly utilised in the literature, for instance in Petrin and Levinsohn (2012), De Loecker and Warzynski (2012), and Newman et al. (2015). Petrin, Poi and Levinsohn (2004) introduce two cases that apply the method by Levinsohn and Petrin (2003): a production function using value added and a production function using gross output.

³⁵We also check for collinearity of labour with material and capital stock by using the STATA user-written command *collin*. The results of the variance inflation factor ($VIF = \frac{1}{1 - R^2}$) which is less than 3 in our case does not indicate a problem of multicollinearity).

- (iv) Firms are assumed to face the same input and output prices. Hence, in our paper, we estimate TFP by each industry, and assume that within the same industry this assumption holds.

Following Levinsohn and Petrin (2003), we estimate equation (A.6) in two steps by using `levpet` which is a Stata command written by Petrin, Poi and Levinsohn (2004). The explanation of the algorithm is as follows:

In the **first step**, making the assumption that

$$\omega_{it} = \omega(k_{it}, m_{it}) \quad (\text{A.8})$$

We have

$$\phi(k_{it}, m_{it}) = \beta_0 + \beta_k k_{it} + \omega(k_{it}, m_{it}) \quad (\text{A.9})$$

Since the form of $\phi_{it}(k_{it}, m_{it})$ is unknown, $\phi_{it}(k_{it}, m_{it})$ is estimated by using a third order polynomial approximation in k_{it} and m_{it} : $\phi(k_{it}, m_{it}) = \sum_{n=0}^3 \sum_{j=0}^{3-n} \sigma_{nj} k_{it}^n m_{it}^j$.

We rewrite equation (A.6)

$$va_{it} = \beta_l l_{it} + \phi_{it}(k_{it}, m_{it}) + \varepsilon_{it} \quad (\text{A.10})$$

This first step aims to estimate the consistent coefficient of l_{it} in the no-intercept OLS (equation A.10). It is assumed that $E[\varepsilon_{it}|l_{it}, k_{it}, m_{it}] = 0$.³⁶

In the **second step**, coefficients estimated in the first step are used to identify β_k . From equation (A.9), we see that $\widehat{\omega}_{it}$ can also be expressed as

$$\widehat{\omega}_{it} = \widehat{\phi}_{it} - \beta_k^* k_{it} \quad (\text{A.11})$$

With the grid search, for each β_k^* we can define the appropriate $\widehat{\omega}_{it}$. Using the value $\widehat{\omega}_{it}$ from equation A.11, Levinsohn and Petrin (2003) approximate $E[\omega_{it}|\widehat{\omega}_{i,t-1}]$ with a third-degree polynomial. With $\widehat{\beta}_l$ derived in the first step, $E[\omega_{it}|\widehat{\omega}_{i,t-1}]$ and β_k^* , rearranging equation A.4 and combining it with the first-order Markov process, the sample residual of the production function is equal to

$$\varepsilon_{it} + \widehat{\xi}_{it} = va_{it} - \widehat{\beta}_l l_{it} - \beta_k^* k_{it} - E[\omega_{it}|\widehat{\omega}_{i,t-1}] \quad (\text{A.12})$$

The solution to find $\widehat{\beta}_k$ is

³⁶Being different from Olley and Pakes (1996), Levinsohn and Petrin (2003) accumulate capital stock by using current investment value $K_{i,t} = (1 - \delta)(K_{i,t-1}) + I_{i,t}$.

$$\min_{\beta_k^*} \sum_{it} (va_{it} - \hat{\beta}_l l_{it} - \beta_k^* k_{it} - E[\omega_{it} | \widehat{\omega}_{i,t-1}])^2 \quad (\text{A.13})$$

This yields a consistent estimate of β_k since $E[(\varepsilon_{it} + \xi_{it}) | k_{it}] = 0$, and because k_{it} was chosen at time $t - 1$ by the accumulation of $k_{i,t-1}$ and $i_{i,t}$ (Levinsohn and Petrin, 2003).

After obtaining consistent coefficients β_k and β_l , the $\log(\text{TFP})$, $\widehat{\omega}_{it}$ can be computed as follows (Olley and Pakes, 1996; Van Beveren, 2012; Newman et al., 2015)

$$\widehat{\omega}_{it} = va_{it} - \hat{\beta}_k k_{it} - \hat{\beta}_l l_{it} \quad (\text{A.14})$$

Table A.1 specifies how the main variables are constructed using available firm level information from the Vietnamese Enterprise Survey. Value added is calculated by the addition method using firm-level records on profit, wage bills, and indirect tax³⁷ and depreciation (see Ha and Kiyota, 2014). The depreciation ratio is assumed to be 10%. In addition, different deflators are used to convert the nominal values in the current prices to the base year price which is the year 2000.³⁸

Table A.1: Measurement of Main Variables

Variables	Measurement
Total output (Y_{it})	Total revenue (TR_{it}) at the end of year t
Wage (W_{it})	Total wage paid to employees at the end of year t
Labor (L_{it})	Total employees at the end of year t
Capital Stocks (K_t)	Net booked values of fixed assets at the end of year t,
Profit (Π_{it})	Total profit before taxes at the end of year t
Value Added (VA_{it})	$\Pi_{it} + W_{it} + \text{indirecttax}_{it} + \text{depreciation}_{it}$
Materials and Services (MS_{it})	$TR_{it} - \Pi_{it} - W_{it} - (K_{it} - K_{i,t-1})$
Total Cost (TC_{it})	$TR_{it} - \Pi_{it}$
Depreciation ($Depre_{it}$)	$K_{it} * \frac{\text{depreciationratio}}{1 - \text{depreciationratio}}$

Notes: Authors' compilation using data drawn from the Vietnamese Enterprise Survey 2005–2010.

B Data Appendix

³⁷The indirect tax is the difference between the total tax paid by the firm and its income tax. See Ha and Kiyota (2014).

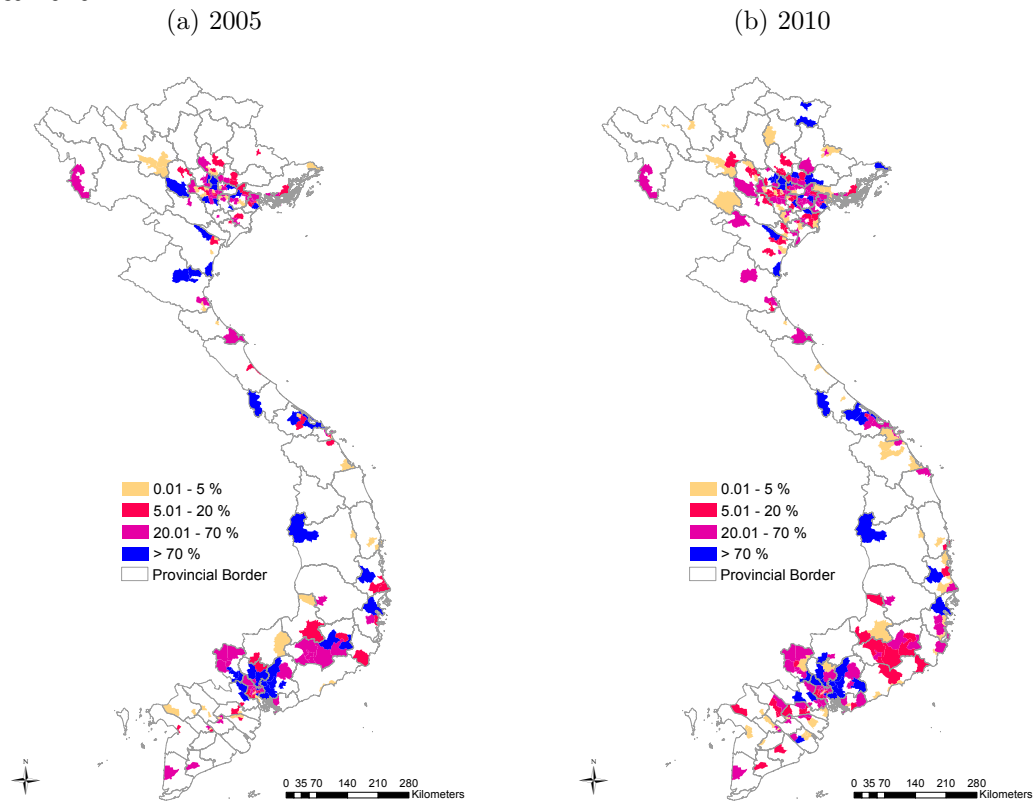

³⁸Specifically, the producer price index of each industry is the deflator for output and value added. We calculate the index by using the annual producer price index (PPI) by industry provided by the General Statistic Offices of Vietnam (GSO; www.gso.gov.vn). Capital stocks are converted to the base year price by the gross fixed capital formation deflators which are calculated using the annual nominal gross fixed capital formation values of Vietnam provided by the World Bank country database available at www.worldbank.org. Nominal values of materials and services are deflated using the annual GDP deflators downloaded from the World Economic Outlook database available at www.imf.org.

Notes: Authors' compilation using data drawn from the Vietnamese Enterprise Survey 2005–2010. Names of industries are shortened, further details are provided on:
<http://www.gso.gov.vn/default.aspx?tabid=512&idmid=5&ItemID=10752>.

Figure B.1: Shares of Total Revenue of Foreign Invested Firms by District in Vietnam 2005 & 2010

Notes: The share of total revenue of foreign invested firms per district is equal to the revenue of foreign invested firms in the district over the total revenue of all firms. The maps are based on authors' calculations using the Vietnam Enterprise Survey 2005 & 2010. Administrative boundaries are based on Global Administrative Areas data (www.gadm.org). Several Vietnamese islands (e.g. Hoang Sa and Truong Sa) are not displayed due to the limitation of the GADM administrative boundaries data.

Figure B.3: Shares of Total Labor Force of Foreign Invested Firms by District in Vietnam 2005 & 2010

Notes: The share of total labor force of foreign invested firms per district is equal to the number of workers of foreign invested firms in the district over the total number of workers of all firms. The maps are based on authors' calculations using the Vietnam Enterprise Survey 2005 & 2010. Administrative boundaries are based on Global Administrative Areas data (www.gadm.org). Several Vietnamese islands (e.g. Hoang Sa and Truong Sa) are not displayed due to the limitation of the GADM administrative boundaries data.

Table B.2: Variable Description & Data Sources

Variable	Description	Source
Dependent Variable		
$\Delta \log(TFP_{ik,t})$	$\log(TFP_{ik,t}) - \log(TFP_{ik,t-1})$ Annual growth in total factor productivity	Own calculations based on Levinsohn and Petrin (2003) and Petrin, Poi and Levinsohn (2004). Source: Vietnamese Enterprise Survey 2005–2010.
Main Explanatory Variables		
Horizontal Linkages:		
$\Delta \log$ No. of FDI Firms	$\log(\sum_{j=1}^N firm_{jk,t}^{RD}) - \log(\sum_{j=1}^N firm_{jk,t-1}^{RD})$ Annual change in the number of foreign firms j in industry k within radius RD around each firm i	Own calculations based on sample of geo-referenced firms. Source: Vietnamese Enterprise Survey 2005–2010.
$\Delta \log$ Tot. Rev. of FDI Firms	$\log(\sum_{i=1}^N TR_{jk,t}^{RD}) - \log(\sum_{i=1}^N TR_{jk,t-1}^{RD})$ Annual change in the sum of total revenue of foreign firms j in the same industry k within circle of radius RD around each domestic firm i	Own calculations based on sample of geo-referenced firms. Source: Vietnamese Enterprise Survey 2005–2010.
Vertical Linkages:		
$\Delta \log$ FWL Manufacturing	$\log(\sum_{i=1}^N \alpha_{fk} TR_{jf,t}^{RD}) - \log(\sum_{i=1}^N \alpha_{fk} TR_{jf,t-1}^{RD})$ Annual change in the forward linked foreign manufacturing firms in industries f within circle of radius RD around each domestic firm i ; α_{fk} is the coefficient measuring the link in the input-output table.	Own calculations based on geo-referenced firms of the Vietnamese Enterprise Survey 2005–2010 and the GSO input-output table (2007).
$\Delta \log$ BWL Manufacturing	$\log(\sum_{i=1}^N \beta_{kb} TR_{jb,t}^{RD}) - \log(\sum_{i=1}^N \beta_{kb} TR_{jb,t-1}^{RD})$ Annual change in the forward linked foreign manufacturing firms in industries b within circle of radius RD around each domestic firm i ; β_{kb} is the coefficient measuring the backward link from upstream industry k to downstream industry b in the input-output table.	Own calculations based on geo-referenced firms of the Vietnamese Enterprise Survey 2005–2010 and the GSO input-output table (2007).
$\Delta \log$ FWL Services	$\log(\sum_{i=1}^N \alpha_{fk} TR_{jf,t}^{RD}) - \log(\sum_{i=1}^N \alpha_{fk} TR_{jf,t-1}^{RD})$ Annual change in the forward linked foreign service firms in industries f within circle of radius RD around each domestic firm i ; α_{fk} is the coefficient measuring the forward link from upstream industry f to downstream industry k in the input-output table.	Own calculations based on geo-referenced firms of the Vietnamese Enterprise Survey 2005–2010 and the GSO input-output table (2007).
$\Delta \log$ BWL Services	$\log(\sum_{i=1}^N \beta_{kb} TR_{jb,t}^{RD}) - \log(\sum_{i=1}^N \beta_{kb} TR_{jb,t-1}^{RD})$ Annual change in the forward linked foreign service firms in industries b within circle of radius RD around each domestic firm i ; β_{kb} is the coefficient measuring the backward link from upstream industry k to downstream industry b in the input-output table.	Own calculations based on geo-referenced firms of the Vietnamese Enterprise Survey 2005–2010 and the GSO input-output table (2007).
Control Variables		
$\Delta \log$ No. of Dom. Firms	$\log(\sum_{d=1}^D firm_{dk,t}^{RD}) - \log(\sum_{d=1}^D firm_{dk,t-1}^{RD})$ Annual change in the number of domestic firms d in the same industry k within radius RD around each firm i	Own calculations based on sample of geo-referenced firms. Source: Vietnamese Enterprise Survey 2005–2010.
$\Delta \log$ No. of FDI Firms in Oth. Ind.	$\log(\sum_{j=1}^J firm_{j,-k,t}^{RD}) - \log(\sum_{j=1}^J firm_{j,-k,t-1}^{RD})$ Annual change in the number of foreign firms j in all other industries $-k$ within radius RD around each firm i	Own calculations based on sample of geo-referenced firms. Source: Vietnamese Enterprise Survey 2005–2010.
$\Delta \log$ No. of Dom. Firms in Oth. Ind.	$\log(\sum_{d=1}^D firm_{d,-k,t}^{RD}) - \log(\sum_{d=1}^D firm_{d,-k,t-1}^{RD})$ Annual change in the number of domestic firms d in all other industries $-k$ within radius RD around each firm i	Own calculations based on sample of geo-referenced firms. Source: Vietnamese Enterprise Survey 2005–2010.
$\Delta \log$ Labor Force	$\log(\sum_{i=1}^N L_{i,t}^{RD}) - \log(\sum_{i=1}^N L_{i,t-1}^{RD})$ Annual change in the labor force measured as number of employees of all firms i in all industries within radius RD around each firm i	Own calculations based on sample of geo-referenced firms. Source: Vietnamese Enterprise Survey 2005–2010.
ΔHHI	$\sum_{i=1}^N RS_{ik,t}^2 - \sum_{i=1}^N RS_{ik,t-1}^2$ Annual change the Herfindahl-Hirschman-Index, measuring the concentration in industry k ; RS is the revenue share of firm i in industry k	Own calculations. Source: Vietnamese Enterprise Survey 2005–2010.

Note: Additional control variables not shown in the table are forward and backward linkages to domestic firms. They are constructed identically as the forward and backward links to foreign firms.

Province-Time FE	Yes	Yes	Yes	Yes	Yes

Notes: Dependent Variable is annual TFP growth, defined as $\log(TFP_{ik,t}) - \log(TFP_{ik,t-1})$. Our main explanatory variable is $\Delta \text{Log No. of FDI firms}$, defined as the annual change of the log of number of foreign invested firms within a circle of radius RD . Estimations include a lagged dependent variable $\Delta \log(TFP_{i,t-1})$ that is instrumented with its lagged value in levels $\log(TFP_{ik,t-2})$. The control variables (Panels B, C, and D) are measured for each firm within a circle of radius RD over time, and calculated as annual change in logarithms. They include the number of domestic firms in the same industry k , the number of foreign firms in all other manufacturing industries, the number of domestic firms in all other manufacturing industries, and the labor force (total number of workers) of all manufacturing industries. Further included is the annual change of the Herfindahl-Index at the industry level. All estimations include year fixed effects, province-year fixed effects, and industry fixed effects. Huber-White standard errors in parentheses are clustered at the industry level. + $p < 0.10$, * $p < 0.05$, ** $p < 0.01$ *** $p < 0.001$.
